Experimental Procedures

General Information

Synthesis and General Instrumentation: Unless otherwise stated, reagents and solvents were purchased from commercial sources and used without further purification. Cholic acid derivative **21a** was synthesized according to a literature procedure.^[1]

Analytical Thin Layer Chromatography (TLC) was carried out using aluminium-backed Merck Kieselgel KG60 F254 silica plates. The plates were visualized by irradiation with short-wave ultraviolet light. Flash chromatography was performed on Grace Davidson Davisil LC60A 40-63 micron silica gel.

All light-promoted halogenation reactions were performed using a custom-built blue LED photoreactor (Figure S1). The custom reactor was comprised of a square metal frame (100 mm × 110 mm) with 14 blue LEDs (2 × SP-02-V4 LED assembly, each consisting of 7 LXML-PR02-A900 Royal-Blue LUXEON Rebel ES LEDs; www.luxeonstar.com). The photoreactor was fitted with PC cooling fans and heat sinks for temperature control (internal temperature of the reactor typically reaches 27 ± 5 °C overnight). The power of the light source can be varied using an intensity control.

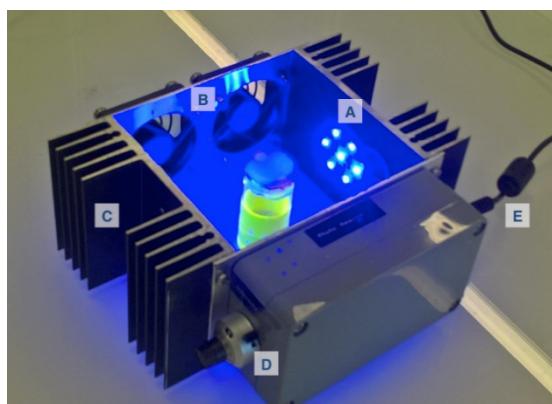

Figure S1. Custom-built LED photoreactor; a) blue LED assembly; b) PC cooling fans; c) heat sinks; d) intensity control; e) 12 V power supply.

¹H NMR and ¹³C NMR spectra were recorded on Bruker 400 Ultrashield (400 MHz), Bruker 500, Ascend 400 (400 MHz) or Varian MR-400. Chemical shifts are expressed in parts per million (PPM) and are referenced to the internal solvent peaks.

Mass spectrometric analyses were performed on a Thermo Scientific Q Exactive mass spectrometer fitted with an ASAP ion source. Positive ions were recorded in an appropriate mass range at 140,000 mass resolution. The APCI probe was used without flow of solvent. The nitrogen nebulizing/desolvation gas used for vaporization was heated to 350 °C in these experiments. The sheath gas flow rate was set to 25, the auxiliary gas flow rate to 5 and the sweep gas flow rate to 2 (all arbitrary units). The discharge current was 4 mA and the capillary temperature was 320 °C.

UV-Vis Spectroscopy: Absorption spectra were measured using a Perkin Elmer Lambda 1050 spectrometer. Steady-state luminescent spectra were recorded using a Perkin Elmer LS50 fluorimeter. Samples were excited at 400 nm, slit widths were 2.7 nm and the area under the spectra were used for determining the Stern-Volmer quenching values.

Electrochemistry: The cell comprised a cylindrical glass vessel with a flat base and custom-built Teflon lid^[2] with holes to fit the electrodes (glassy carbon working (CH Instruments), platinum wire counter and either silver wire or ‘leakless’ Ag/AgCl (eDAQ) reference). The cell was housed in a light-tight Faraday cage. Potentials were applied using an Autolab PGSTAT204 potentiostat, and referenced *in situ* to the ferrocenium/ferrocene ($\text{Fc}^{+/0}$) couple, and converted to the reported reference (SCE) using $\text{Fc}^{+/0} = +0.4 \text{ V}$.^[3] Freshly distilled acetonitrile with 0.1 M TBAPF₆ supporting electrolyte was used as the solvent. Electrodes were cleaned/polished prior to each experiment. The working electrodes were polished using 0.05 µm alumina powder on a felt pad with deionized water. All electrodes were rinsed with deionized water, ethanol and acetone. The solvent was degassed with nitrogen or argon for 5 minutes.

Steady-State UV-Vis Spectroscopy

The stock solution of palladacycle **1** in acetonitrile (0.01 M) was diluted to a given concentration in volumetric flasks, and then transferred to a septum-capped quartz cuvette.

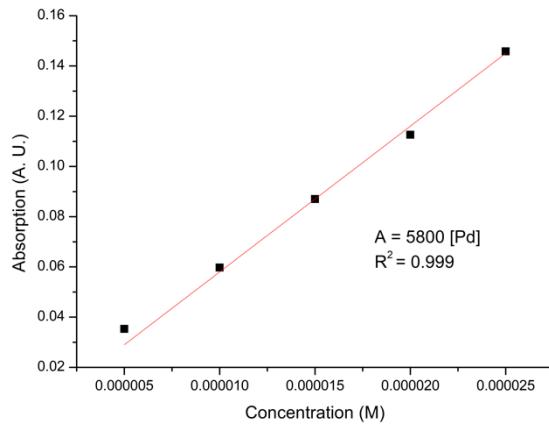

Figure S3: Extinction coefficient calibration curve at 272 nm (**A**) and 417 nm (**B**) for palladacycle **1** in acetonitrile.

The emission spectra were recorded under air (septum-capped quartz cuvette prior to any degassing) to give a single emission band at $\lambda_{\text{max}} = 530$ nm. The sample was then sparged with argon for approximately 15 minutes, while care was taken to avoid evaporation of solvent. Emission at $\lambda_{\text{max}} = 530$ nm was found not to be oxygen-sensitive; however, a second, overlapping emission band at $\lambda_{\text{max}} = 625$ nm was observed in the absence of oxygen.

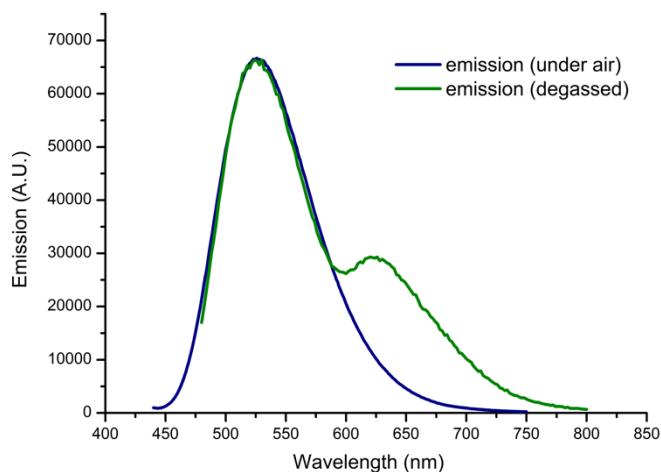

Figure S4: Photoluminescence emission spectra of palladacycle **1** in acetonitrile (20 μm) collected at room temperature, under air (blue) and after sparging with argon for 15 minutes (green). Excitation wavelength = 430 nm. Slit widths = 4 nm.

Stern-Volmer Fluorescence Quenching Studies

Samples for steady-state photoluminescence were prepared in the following manner: quencher was added to an acetonitrile solution of palladacycle **1** (0.01 mM) and made to a given concentration in a volumetric flask. The solution was then transferred to a septum-capped quartz cuvette. To observe quenching of the triplet excited state, the solution was deoxygenated immediately prior to measurement by sparging with argon for approximately 10 min. Fluorescence quenching studies were performed under air.

Palladacycle 1

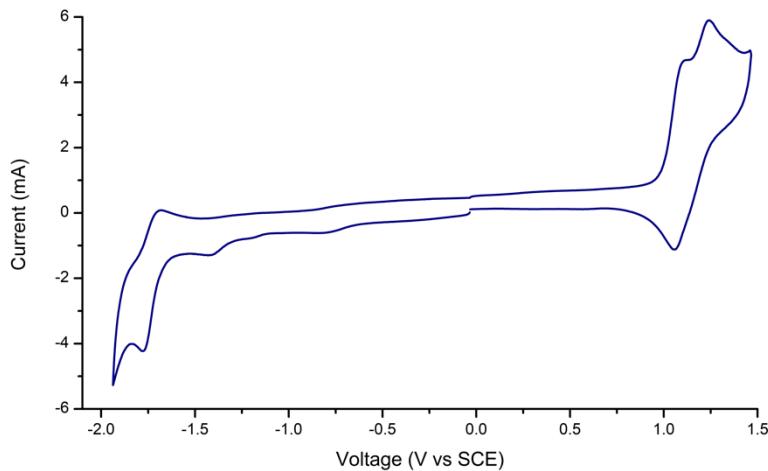

Figure S7: Cyclic voltammogram of palladacycle **1** ($1 \mu\text{M}$) measured in degassed acetonitrile (Bu_4NPF_6 as the supporting electrolyte), scan rate = 0.1 Vs^{-1} , reported relative to SCE using $\text{Fe}^{+/-}$ couple as an internal standard; reference electrode Ag^+/Ag , working electrode: glassy carbon; auxiliary electrode: Pt wire.

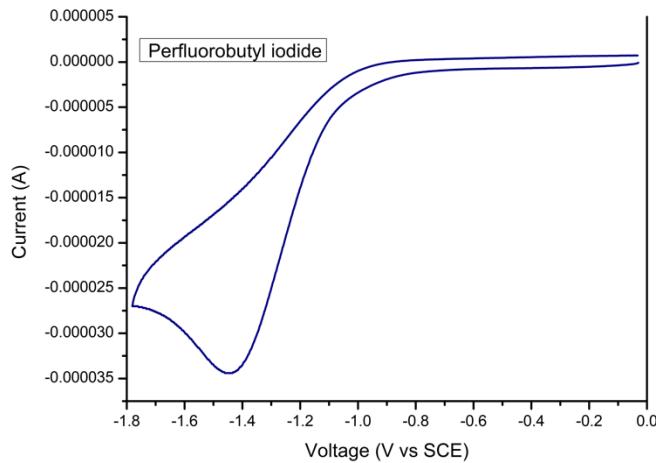

Two closely overlapping oxidation waves were observed at $E_p = 1.10$ and 1.24 V and a reduction wave was observed at $E_p = -1.78 \text{ V}$. ΔE_p values, ($\Delta E_p > 0.059$) suggest that both oxidation and reduction are quasi-reversible one-electron processes.^[4]

Gas-Phase Mass Spectrometry Experiments (Photoreaction Screening)

The experiments were conducted using two different mass spectrometers equipped with electrospray ionization (ESI) sources. ESI high resolution mass spectra (HRMS) were collected on a Thermo OrbiTrap Fusion Lumos mass spectrometer. Tandem mass spectrometry experiments (MS/MS) were performed on a Thermo Scientific (Bremen, Germany) linear ion trap (LTQ). For both sets of mass spectrometry experiments the charge tag complex **4** was applied using the standard iodination protocol in continuous flow (20 min retention time), which was then infused directly into the ESI source to access online reaction monitoring platform (Figure S9). The reaction mixture was prepared in acetonitrile (100 μ M) and pumped into the electrospray source through the 448 nm LED photoreactor (Figure S1). The progress of the reaction was monitored (I) in the absence of oxone and (II) in the presence of oxone. Furthermore MS/MS data were collected to gain structural information of the newly formed intermediates by fragmenting the precursor ions.

Typical electrospray source conditions were:

CID: Sheath Gas = 10 arbitrary units, Auxiliary Gas = 5 arbitrary units, Sweep Gas = 0 arbitrary units, Spray Voltage = 4 kV, Capillary Temp. = 250 °C, Capillary Voltage = 2 V, Tube Lens Voltage = 75 V. The precursor ion was mass selected with a window of 1 m/z and collision induced dissociation was carried out using the helium bath gas by activating the ion with an activation time of 30 ms. A normalized collision energy (NCE) was chosen to deplete the precursor ion to 10%.

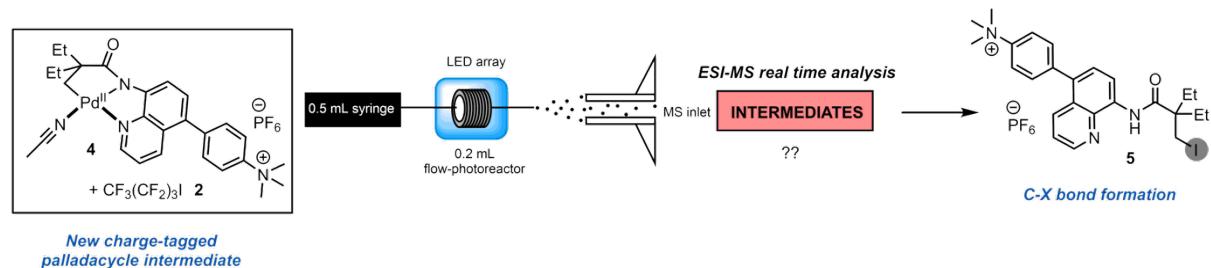

Figure S9: Schematic representation of the real-time photoreaction screening platform using the charge tagged palladacycle **4**. The progress of the reaction and intermediates were monitored at 100 μ M concentration in acetonitrile on the positive-ion mode with the 448 nm (15 W) blue LED photoreactor.

Computational Studies

Density Functional Theory (DFT) calculations were carried out with the Gaussian09^[5] program. Ground state singlet optimizations were performed on the crystal structure with M06 functional. SDD basis set was chosen for Pd and I while 6-311+G(d) was used for the other atoms. The CPCM formalism for the Self Consistent Reaction Field (SCRF) model of solvation was employed to account for solvation in acetonitrile. All ground and transition states were verified by vibrational frequency analysis at the same level of theory, with all minima showing no imaginary frequencies and all transition states showing only one imaginary frequency. Intrinsic reaction coordinate (IRC) calculations were used to confirm the connectivity between transition structures and minima. The cartesian coordinates and corresponding energies for all optimized ground and transition state structures, including the imaginary frequencies of the transition states are available in the Supporting Information.

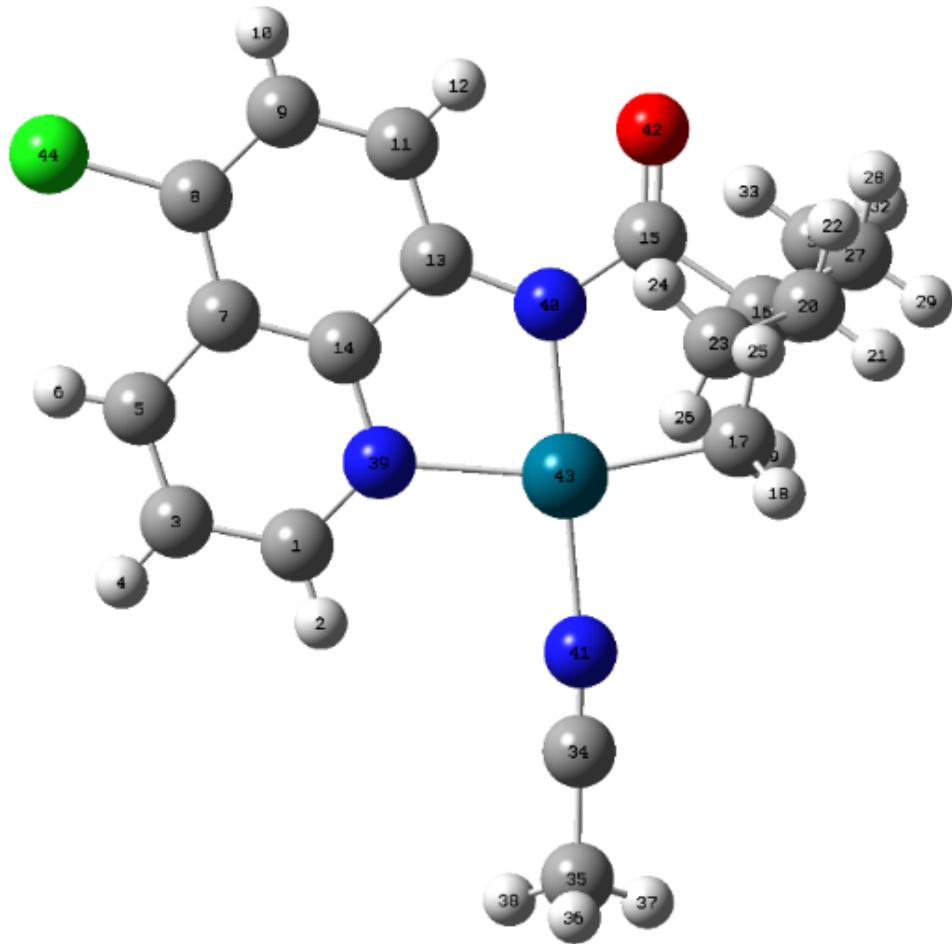

Time-dependent density functional theory (TD-DFT) calculations were performed on the ground state optimized structure to probe the nature of the electronic transitions in acetonitrile. Different combinations of functionals (M06, ω B97X-D, B3LYP) and basis sets were tested and compared with the experimental absorption spectrum. M06/6-311+G(d)/SDD(Pd) provided the best reproducible spectrum to the experimental absorption spectrum (Figure S19).

Molecular orbital analysis were performed at the BP86/def2-TZVP level,^[6] which has been shown to give realisable results. QMForge program was used to analyse the molecular orbitals at the ground state and the triplet excited states.

Thermodynamics of the Reductive Elimination Step

Thermodynamics of the reductive elimination steps in acetonitrile were computed using M06/6-311G(d)/SDD(Pd) and results are summarised in Figure S23, S24 and S25.

Synthesis and Characterization

5-Chloro-8-aminoquinoline

Pyridine (3 drops) was added to a solution of 8-aminoquinoline **32** (3.0 g, 20.8 mmol) in acetic anhydride (26 mL). The reaction mixture was stirred at room temperature for 12 hours. It was then quenched with saturated aqueous NaHCO₃ solution, and the mixture was left to stir for 1 hour. It was extracted with CH₂Cl₂ (3×), and the combined organic extracts were washed with brine (3×) and dried (MgSO₄). The solvent was removed under reduced pressure to give *N*-(quinolin-8-yl)acetamide **33** as a yellow solid, which was used without further purification.

Oxone (8.0 g, 26 mmol, 1.5 equiv.) and NaCl (4.1 g, 70 mmol, 4.0 equiv.) were added to a solution of *N*-(quinolin-8-yl)acetamide (3.2 g, 17.5 mmol) in DMF (170 mL). The reaction flask was sealed and heated at 130 °C for 12 hours. After cooling to room temperature, the reaction mixture was diluted with water and extracted with EtOAc (3×). The combined organic extracts were washed with saturated aqueous LiCl solution (3×) and dried (MgSO₄). The solvent was removed under reduced pressure to yield **34** a pale brown solid, which was used without further purification.

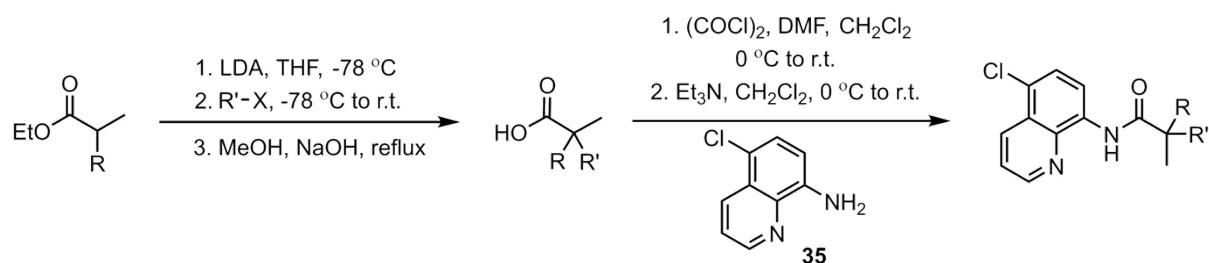

N-(5-Chloroquinolin-8-yl)acetamide **34** (2.7 g, 12.2 mmol) was added to a solution of NaOH (4.8 g, 122 mmol, 10 equiv.) in MeOH (120 mL) and the reaction mixture was heated at reflux for 12 hours. The reaction mixture was cooled to room temperature, extracted with CH₂Cl₂ (3×) and dried (MgSO₄). The solvent was removed under reduced pressure to give a yellow solid. Purification by flash chromatography on deactivated silica, eluting 30% EtOAc/Hexane gave the title compound **35** as a bright yellow solid (1.7 g, 49% yield over 3 steps).

¹H NMR (CDCl₃, 400 MHz): δ = 8.79 (dd, *J* = 4.2, 1.6 Hz, 1H), 8.47 (dd, *J* = 8.5, 1.6 Hz, 1H), 7.49 (dd, *J* = 8.5, 4.2 Hz, 1H), 7.40 (d, *J* = 8.1 Hz, 1H), 6.83 (d, *J* = 8.4 Hz, 1H), 5.02 (br s, 2H).

¹³C NMR (CDCl₃, 100 MHz): δ = 147.9, 143.4, 138.9, 133.0, 127.4, 126.7, 122.2, 118.2, 109.6.

General Procedure for the Preparation of *N*-(5-Chloroquinolin-8-yl) Amides

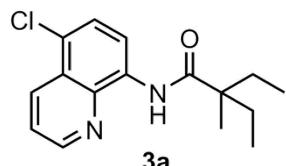

A solution of LDA in THF (C = 2.0 M, 15 mL, 30 mmol, 1.2 equiv.) was added dropwise to a solution of carboxylate ester (3.0 g, 23 mmol, 1.0 equiv.) in THF at -78 °C. The solution was stirred at -78 °C for 3 h. Alkyl halide (2.0 equiv.) was then added dropwise at -78 °C, and the reaction mixture was stirred at room temperature overnight. It was quenched with water and extracted with Et₂O (3×). The combined organic layers were washed with brine (3×) and dried (MgSO₄). The solvent was removed under reduced pressure, and the residue was taken up in MeOH (50 mL) and combined with solid NaOH (9.2 g, 230 mmol, 10 equiv.). The reaction mixture was heated at reflux overnight. After cooling to room temperature, the solution was diluted with water and washed with Et₂O (3×). The aqueous layer was acidified to pH 1 with 3 M aqueous HCl solution and extracted with CH₂Cl₂ (3×), and dried (MgSO₄). The solvent was removed under reduced pressure to give the crude carboxylic acid, which was used directly for the next step without further purification.

Oxalyl chloride (5.04 mmol, 0.43 mL, 1.8 equiv.) was added dropwise to a solution of the carboxylic acid (4.2 mmol, 1.5 equiv.) in CH₂Cl₂ (5 mL) and DMF (3 drops) at 0 °C. The reaction mixture was stirred at room temperature overnight. The solvent was removed under reduced pressure, and the residue dried under vacuum, taken up in CH₂Cl₂ (5 mL) and added dropwise to a solution of 5-chloro-8-aminoquinoline **35** (0.5 g, 2.8 mmol, 1.0 equiv.) and Et₃N (0.6 mL, 4.2 mmol, 1.5 equiv.) in CH₂Cl₂ (5 mL) at 0 °C. The reaction mixture was stirred at room temperature for 5 h. It was diluted with CH₂Cl₂, washed with brine (3×) and dried (MgSO₄). The solvent was removed under reduced pressure, and the

residue was purified by flash chromatography on deactivated silica, eluting with EtOAc/n-pentane), to give the *N*-(5-chloroquinolin-8-yl)amides.

General Procedure for the Iodination Reaction

Procedure A:

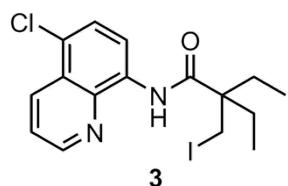

Cyclopalladated complex (0.1 mmol) and oxone (30.7 mg, 0.1 mmol) were placed in a pressure relief sample vial and taken up in MeCN (1 mL). The reaction mixture was sparged with N₂ for 5 minutes. Perfluorobutyl iodide (0.1 mmol, 1 equiv.) was added via air-tight syringe and the solution was sparged with N₂ for 1 minute. The cap was wrapped in parafilm and the reaction mixture was stirred for 16 hours at room temperature, whilst being irradiated with 15 W Blue LEDs. The reaction mixture was diluted with CH₂Cl₂ and washed with brine. The aqueous layer was re-extracted with CH₂Cl₂ (3×) and dried (MgSO₄). The solvent was removed under reduced pressure and the residue was purified by flash chromatography on deactivated silica, eluting 10-20% EtOAc/hexane.

Procedure B:

Amide (0.1 mmol) and $\text{Pd}(\text{OAc})_2$ (0.1 mmol) were placed in a pressure relief sample vial and dissolved in acetonitrile (1 mL). The solution was stirred at room temperature for 3 hours. Oxone (30.7 mg, 0.1 mmol) was added and the reaction mixture was sparged with N_2 for 5 minutes. Perfluorobutyl iodide (0.1 mmol, 1 equiv.) was added via air-tight syringe and the solution was sparged with N_2 for 1 minute. The cap was wrapped in parafilm and the reaction mixture was stirred for 16 hours at room temperature, whilst being irradiated with 15 W Blue LEDs. The reaction mixture was diluted with CH_2Cl_2 and washed with brine. The aqueous layer was re-extracted with CH_2Cl_2 ($3\times$) and dried (MgSO_4). The solvent was removed under reduced pressure and the residue was purified by flash chromatography on deactivated silica, eluting 10-20% EtOAc/hexane.

General Procedure for the Bromination Reaction

Cyclopalladated complex (0.1 mmol), ethyl tribromoacetate (32.4 mg, 0.1 mmol) and oxone (30.7mg, 0.1 mmol) were placed in a pressure relief sample vial and taken up in MeCN (1ml). The reaction mixture was sparged with N₂ for 1 minute. The cap was wrapped in parafilm and the reaction mixture was stirred for 16 hours, whilst being irradiated with 15W Blue LEDs at room temperature. The reaction mixture was diluted with CH₂Cl₂ and washed with brine. The aqueous layer was re-extracted with CH₂Cl₂ (3×) and dried (MgSO₄). The solvent was removed under reduced pressure and the residue

was purified by flash chromatography on deactivated silica, eluting 10-20% EtOAc/hexane.

X-Ray Data

A yellow plate like crystal was mounted on a XtaLAB Synergy, Dualflex, HyPix diffractometer employing mirror monochromated Mo K α radiation generated from a micro-focus sealed X-ray tube. Cell constants were obtained from a least squares refinement against 7049 reflections located between 5.53 and 70.69° 2 θ . Data were collected at 99.95(15) Kelvin.

The structure was solved in the triclinic space group *P*-1 by direct methods with SHELXT,^[9] and extended and refined with SHELXL-2016/6.^[9] The non-hydrogen atoms in the asymmetric unit were modelled with anisotropic displacement parameters. A riding atom model with group displacement parameters was used for the hydrogen atoms.
