## 1. General information

All the chemicals used in synthesis are analytically pure and were used as received. Solvents were dried and distilled before used for synthesis. ${ }^{1} \mathrm{H}$ chemical shifts are reported in parts per million (ppm) relative to TMS, with the residual solvent peak used as an internal reference. The mass spectra were measured by TOF MS MALDI spectrometer.

## 3. Singlet Oxygen Photosensitizing Measurement

The ${ }^{1} \mathrm{O}_{2}$ quantum yields $\left(\Phi_{\Delta}\right)$ of the photosensitizers (PBI-Cz dyads) were measured with 2,6diiodobodipy as standard $\left(\Phi_{\Delta}=0.83\right.$ in DCM$)$. The absorbance of the ${ }^{1} \mathrm{O}_{2}$ scavenger $1,3-$ diphenylisobenzofuran (DPBF) was adjusted around 1.0 in air saturated dichloromethane. Then, the photosensitizer was added to the solution of DPBF, and the photosensitizer's absorbance was adjusted around $0.2-0.3$. The solution in the cuvette was irradiated with monochromatic light at the peak absorption wavelength for 10 s . Then the absorbance at 414 nm was measured after each irradiation. The slope of plots of absorbance of DPBF at 414 nm vs irradiation time for each photosensitizer was calculated. Singlet oxygen quantum yields $\left(\Phi_{\Delta}\right)$ were calculated according to the following equation:

$$
\phi_{\Delta, \text { sam }}=\phi_{\Delta, s t d}\left(\frac{1-10^{A_{s t d}}}{1-10^{A_{s a m}}}\right)\left(\frac{m_{s a m}}{m_{s t d}}\right)\left(\frac{\eta_{\text {sam }}}{\eta_{s t d}}\right)^{2}
$$

Where 'sam' and 'std' designate the photosensitizers and 2,6-diiodobodipy, respectively, $A$ stands for absorbance, $m$ is the slope of the curves of absorbance of DPBF (414 nm) vs the irradiation time, $\eta$ is refractive index of the solvent.
