Experimental Section

General. Gel permeation chromatography (GPC) was performed on a Waters GPC machine using an isocratic HPLC pump (1515) and a refractive index detector (2414). THF was used as the eluent (flow rate= 1.0 mL min⁻¹). Waters styragel HR2, HR3, HR4 (7.8 x 300 mm) were employed using polystyrene as standard (M_n values range from 375 to 3.5 x 10⁶). Absorption spectra and emission spectra (1x 10⁻⁵ M) were measured with Hitachi U-3310 and Hitachi F-4500 fluorescence spectrophotometers, respectively. Quantum yield was obtained using coumarin-I in EtOAc as reference (Φ = 0.99).

1,4-Bis-(2-di[isopropyl]silanylvinyl)benzene (3b). Under N₂, to a solution of **5**⁸ (0.58 g, 2.0 mmol) in THF (50 mL) cooled at -78 °C was added slowly ⁷BuLi (5.4 mL, 1.55 M in pentane, 8.4 mmol). After stirring for 30 min at -78 °C, chlorodiisopropylsilane (0.7 mL, 4.2 mmol) was added and the mixture was gradually warmed to rt, stirred for 3 h, and quenched with H₂O (5.0 mL). The aqueous layer was extracted with Et₂O (3 × 20 mL), and the organic layer was washed with brine (20 mL), dried (MgSO₄), filtered, and evaporated in vacuo to give the residue which was chromatographed on silica gel (CH₂Cl₂/hexane 1 : 4) to afford **3b** (0.60 g, 82 %) as a white solid: mp 45-46 °C (pentane); ¹H NMR (400 MHz, CDCl₃): δ 1.04-1.08 (m, 28 H), 3.73-3.75 (m, 2 H), 6.39 (dd, *J* = 19.1 Hz, 4.7 Hz, 2 H), 7.03 (d, *J* = 19.1 Hz, 2 H),

Time Resolved Fluorescence Measurements. A mode-locked tunable Ti:sapphire laser (Coherent, Mira 900 operating at $\lambda = 900$ nm, 76 MHz pulse rate) was passed through a third harmonic generator to generate the $\lambda = 300$ nm as the excitation light source. The fluorescence of sample was reflected by a grating (150g/mm; BLZ: 500 nm) and detected by an optically triggered streak camera (Hamamatsu C5680) with a time resolution of about 5 ps.

STM (scanning tunneling microscopy) Characterization.

STM imaging of polymers **1a₁** and **1b₁** was carried out with a NanoScope IIIa controller equipped with a low-current converter for experiments requiring high

tunneling impedance (Veeco Metrology Group/Digital Instruments, USA). The STM probes were commercially available Pt/Ir tips (PT, Nanotips, Veeco Metrology Group/Digital Instruments, USA). To observe individual polymers, a relatively diluted solution was prepared by dissolving 1- μ g/mL **1a₁** or **1b₁** in hexane (ca. 0.25 μ M). The polymers were drop-cast onto freshly cleaved HOPG (highly orientated pyrolytic graphite, grade ZYD, Advanced Ceramics Corp., USA), subjected to vacuum-dry (\sim 30 min, 120 mTorr) to remove trace amount of solvent, and rapidly transferred to a chamber where dry N₂ was purging throughout the experiments and the humidity was lower than 2%. Typical imaging conditions were 0.5~1.2 V in bias voltage and 10~50 pA in tunnelling current. The dimensions of images were calibrated by the unit cell vectors of the underlying HOPG. The large panels of Figure 4 were raw data. To better present the detail structure of polymer **1b₁**, the inset of Figure 4b was FFT-filtered (fast Fourier Transform) by removal of signal contributed from HOPG lattice. 17-20 bright spots (divinylbenzene moieties) can therefore be addressed (for example, Figure S7b) with the absence of HOPG features. Shown below is Figure S7 to demonstrate that the filtering procedure does not alter the morphological characteristics of polymer **1b₁**.

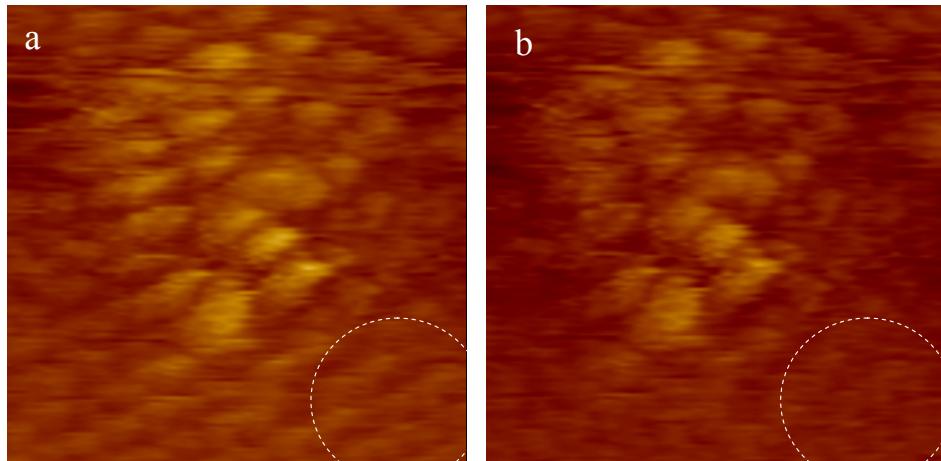

Fig. S7. STM images of **1b₁**. (a) Raw image and (b) FFT-filtered image. The white circles indicate that the removal of HOPG features facilitates counting the number of divinylbenzene moieties in the images. Conditions: image size, 3.1 x 3.1 nm; bias voltage, 0.50 V; tunnelling current, 33 pA.
