DETAILS OF THE DFT STUDIES

Calculations have been performed with the Gaussian03 package¹ using the hybrid functional B3PW91.^{2,3} The Ti atom was represented by the pseudo-potential of Dolg et al. and the associated basis set,⁴ augmented by an f polarization function.⁵ The other atoms (C, H, N, and P) were treated with the 6-31G(d,p) basis set.⁶ Full optimizations without any symmetry constraint were performed followed by analytical computations of the Hessian matrix to characterize the extrema located as minimum or transition state. The NMR calculations were performed in the GIAO approximation^{7,8} using IGLOO-II basis sets for C, N, H, and P and the Ahlrichs TZP basis set for Ti.⁹ The ^{31}P chemical shifts were expressed assuming a value of -69 ppm for the calculated free ^tBuCP.
