## Instrumentations

NMR spectra were recorded on Bruker DPX200 ( 200 MHz and 50 MHz for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$, respectively), Bruker DMX300 ( 300 MHz and 75 MHz for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$, respectively) and Varian inova 400 spectrometers. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ chemical shifts $(\delta)$ are reported in parts per million (ppm) relative to a residual proton peak of the solvent, $\delta=3.31$ for $\mathrm{CD}_{3} \mathrm{OD}, \delta=7.26$ for $\mathrm{CDCl}_{3}$, and $\delta=4.79$ for $\mathrm{D}_{2} \mathrm{O}$. Multiplicities are reported as: s (singlet), d (doublet), t (triplet), q (quartet), dd (doublet of doublets), dt (doublet of triplets), dq (double quartet), ddd (double, double doublet), ddt (double, double triplet) or m (multiplet). Broad peaks are indicated by br. Coupling constants are reported as a $J$ value in Hertz (Hz). The number of protons ( n ) for a given resonance is indicated as nH , and is based on spectral integration values. ${ }^{13} \mathrm{C}$ NMR chemical shifts ( $\delta$ ) are reported in ppm relative to $\mathrm{CD}_{3} \mathrm{OD}\left(\delta=49.0\right.$ ) or $\mathrm{CDCl}_{3}(\delta=$ 77.0). Electrospray LC/MS analysis was performed using a Shimadzu LC/MS 2010A system. Matrix assisted laser desorption/ionisation time-of-flight (MALDI-ToF) spectra were measured on a Bruker Biflex III spectrometer and samples were prepared from MeOH solutions using indoleacrylic acid (IAA) ( $20 \mathrm{mg} / \mathrm{mL}$ ) as a matrix. LCQ/MS analysis was performed using Thermo scientific Advantage LCQ Lineair-lontrap Electrospray (ESI-MS). Electrospray ionisation time-of-flight (ESI-ToF) spectra were measured with a JEOL AccuToF. FT-IR spectra were recorded on an ATI Matson Genesis Series FTIR spectrometer with a fitted ATR cell. The vibrations $(v)$ are given in $\mathrm{cm}^{-1}$. Fluorescence measurents were performed on an Ascent reader, Thermolab systems OY fluorometer equipped with a 390/460 filter set (excitation /emission).

## Methods and materials

Unless otherwise stated, all chemicals were obtained from commercial sources and used without further purification. THF was distilled under nitrogen from sodium/benzophenone, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{EtOAc}$ and $\mathrm{Et}_{2} \mathrm{O}$ were distilled under nitrogen from $\mathrm{CaH}_{2}$. Analytical thin layer chromatography (TLC) was performed on Merck precoated silica gel 60 F-254 plates (layer thickness 0.25 mm ) with visualization by ultraviolet (UV) irradiation at $\lambda=254 \mathrm{~nm}$ and/or $\lambda=366 \mathrm{~nm}$ and/or staining with $\mathrm{KMnO}_{4}$. Purifications by silica gel chromatography were performed using Acros ( $0.035-0.070 \mathrm{~mm}$, pore diameter ca. 6 nm ) silica gel. Preparative thin layer chromatography (Prep-TLC) was performed on Merck precoated silica gel 60 F-254 plates (layer thickness 1.00 mm ) with concentration zone and visualization by UV irradiation at $\lambda=254 \mathrm{~nm}$ and/or $\lambda=366 \mathrm{~nm}$. Counter current distribution was carried out using $n$-butanol and water. Water used in the biological procedures was deionised using a Labconco Water Pro PS purification system. Bovine serum albumin (BSA) was purchased from Sigma, A-7030. Cbz-Gly-Gly-Arg-AMC was purchased from Bachem, l-1140. Human thrombin (h-Flla) and alpha-2-macroglobulin-thrombin complex ( $\alpha_{2} \mathrm{M}-\mathrm{T}$ ) were supplied by Synapse B.V., Maastricht, The Netherlands.

## Synthesis

Boc-Arg-AMC•HCI (I)

To a cold solution $\left(-15^{\circ} \mathrm{C}\right)$ of Boc-protected arginine ( $4.64 \mathrm{~g}, 5.0 \mathrm{mmol}$ ) and 7 -amino-4-methyl-coumarin ( $875 \mathrm{mg}, 5.0 \mathrm{mmol}$ ) in pyridine ( 15 mL ), phosphoryl chloride ( $0.51 \mathrm{ml}, 5.5 \mathrm{mmol}$ ) was added drop wise. A color change going from yellow to orange was observed. The mixture was stirred for 2 hours at $-15{ }^{\circ} \mathrm{C}$ and then allowed to warm to room temperature and was stirred for an additional hour. The reaction mixture was quenched with water ( 15 mL ). The solvents were evaporated under reduced pressure. The crude reaction mixture was purification by counter current chromatography using water as stationary phase and $n$-butanol as mobile phase. The product was obtained as a light yellow powder ( $1.59 \mathrm{~g}, 68 \%$ ). $R_{\mathrm{F}}=0.65$ $\left(n-\mathrm{BuOH} / \mathrm{H}_{2} \mathrm{O} / \mathrm{AcOH} 4: 1: 1 \mathrm{v} / \mathrm{v}\right) .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}\right) \delta(\mathrm{ppm}): 7.70(\mathrm{~d}, \mathrm{~J}=2.13,1 \mathrm{H}), 7.60(\mathrm{~d}$, $J=11.6 \mathrm{~Hz}, 1 \mathrm{H}), 7.38(\mathrm{~d}, \mathrm{~J}=12 \mathrm{~Hz}, 1 \mathrm{H}), 6.13(\mathrm{~d}, \mathrm{~J}=1.6 \mathrm{~Hz}, 1 \mathrm{H}), 4.12(\mathrm{~m}, 1 \mathrm{H}), 3.12(\mathrm{t}, \mathrm{J}=8.8 \mathrm{~Hz}$, $2 \mathrm{H}), 2.36(\mathrm{~s}, 3 \mathrm{H}), 1.59-1.85(\mathrm{~m}, 4 \mathrm{H}), 1.45(\mathrm{~s}, 9 \mathrm{H}) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(50 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}\right) \delta(\mathrm{ppm}): 173.6,163.2$, 158.6, 158.0, 155.2, 143.3, 126.7, 117.2, 113.6, 108.0, 80.9, 56.4, 42.1, 30.6, 28.8, 26.5, 18.6. H-Arg-AMC•2HCI (II)

To a suspension of Boc-Arg-AMC•HCI (I) (1.18 g, 2.53 mmol$)$ in ether $(50 \mathrm{~mL})$, a solution of HCl dissolved in EtOAc ( $2.6 \mathrm{M}, 10 \mathrm{ml}$ ) was added. The suspension was stirred overnight at room temperature after which the solvents were removed in vacuo. The product was re-suspended in $\mathrm{Et}_{2} \mathrm{O}$ ( 20 mL ), stirred for 2 hours and filtered off to yield a white powder ( 993 mg , $97 \%) . ## Macrocyclization reactions

Starting with linear precursor 3a first the 1,3-dipolar cycloaddition was performed in the presence of copper(I) bromide and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in toluene at $40{ }^{\circ} \mathrm{C}$ giving rise to multiple products (Table S1, entry 1). Applying $\mathrm{CuSO}_{4}$ in combination with sodium ascorbate in a solvent mixture of tert-butanol/water again produced multiple products, including the desired cyclic product (Table S1, entry 2). Disturbingly, identification of the crude products with ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy was complicated due to complexation of copper ions to the guanidine moiety giving rise to broadening of the signals. A convenient way to get around this problem involves pressure-promoted cycloaddition in the absence of copper. ${ }^{[57]}$ Hence, a high pressure experiment was performed (DMF, $50^{\circ} \mathrm{C}, 5$ days), but unfortunately again a variety of products was formed (entry 3). The use of copperwire activated by $\mathrm{Et}_{3} \mathrm{~N}$ in a solvent mixture of $\mathrm{MeOH} / \mathrm{MeCN}$ required prolonged heating ( $65{ }^{\circ} \mathrm{C}$, 7 days), leading to the formation of both the desired product and by-products (entry 4).
The macrocyclization reactions performed on compound 3b proceeded more successfully, giving clean conversions to the desired product $\mathbf{2 b}$ according to TLC analysis (Table S1, entries 5 and 6). However, the unprotected side-chain of arginine hindered purification and thus isolation of the product.

## Biological evaluation

Determination kinetic parameters for H-Gly-Pro-Arg-AMC•2HCl (1):
The following solutions were prepared and stored at the indicated temperatures:
Substrate: H-Gly-Pro-Arg-AMC ( $55.7 \mathrm{mg}, 0.1 \mathrm{mmol}$ ) was dissolved in $1.0 \mathrm{~mL} \mathrm{BSA}^{+}$buffer ( $60 \mathrm{mg} / \mathrm{mL}$, containing $\mathrm{NaCl}(8.18 \mathrm{mg} / \mathrm{mL})$ ) to give a 100 mM stock solution. From this stock solution a series of dilutions was prepared (total volume of $500 \mu \mathrm{~L}$ ) to give final substrate concentrations in the well of $0,200,400,600,800,1000,1200$, and $1400 \mu \mathrm{M}$. The dilutions are kept at $37^{\circ} \mathrm{C}$.
Fluo: Cbz-Gly-Gly-Arg-AMC ( $61.5 \mathrm{mg}, 0.1 \mathrm{mmol}$ ) was dissolved in 1.0 mL DMSO to give a 100 mM stock solution. $7.5 \mu \mathrm{~L}$ of the 100 mM stock solution and $292.5 \mu \mathrm{~L}$ BSA60 buffer (NOT containing NaCl ) were shortly vigorously mixed to give a Fluo-solution of 2.5 mM . This solution was kept at room temperature.
$h$-Thrombin: A solution of $1.2 \mu \mathrm{M}$ activated humane thrombin (denoted Flla) was prepared from an $18.8 \mu \mathrm{M}$ Flla stock solution via dilution with BSA5 buffer ( $5 \mathrm{mg} / \mathrm{mL}$ ). The Flla solution was kept at $0^{\circ} \mathrm{C}$. Prior to use it was warmed to $37^{\circ} \mathrm{C}$.
Calibrator: Lyophilized $\mathrm{a}_{2}$-MT complex was reconstituted in 1 mL deionised water to give a final enzyme concentration of 600 nM . The calibrator solution was kept at $0^{\circ} \mathrm{C}$. Prior to use it was warmed to $37^{\circ} \mathrm{C}$.

A set of four wells (quadruple measurement) of an Immulon 2 HB , round-bottom 96 -well plate, was filled with $100 \mu \mathrm{~L}$ of each appropriate substrate concentration (total $4 \times 8$ wells). A set of four wells in a 96 wells plate was filled with $80 \mu \mathrm{~L}$ BSA5 buffer followed by $20 \mu \mathrm{~L}$ of Fluo-solution. The 96 wells plate was placed in a Ascent reader, Thermolab systems OY fluorometer equipped with a 390/460 filter set (excitation lemission) and allowed to warm to $37^{\circ} \mathrm{C}$ (approximately 5 minutes). To all the wells containing substrate, $20 \mu \mathrm{~L}$ of $0.6 \mu \mathrm{M}$ Flla solution was added to each well ( $4 \times 8$ wells) to initiate hydrolysis ( 200 nM end concentration of Flla in wells). To the wells containing the Fluo-solution, $20 \mu \mathrm{~L}$ of calibrator was added to initiate hydrolysis. In a typical experiment fluorescence was measured continuously during 40 minutes at $37^{\circ} \mathrm{C}$. The obtained data was organized in Microsoft Excel and the kinetic parameters were obtained by fitting the data to the Michaels-Menten equation. For the determination of $\mathrm{K}_{\mathrm{M}}$ and $\mathrm{k}_{\text {cat }}$ the initial reaction velocity of the first 10 minutes was used. The amidolytic activity was calculated by comparing the arbitrary fluorescence values to those of an AMC-calibration curve. Results of different experiments can be compared by correcting the amidolytic activity of each experiment with the amidolytic activity found for the calibrator which was measured in the same 96 wells plate.

Determination kinetic parameters for cyclo-[-N-(N-(1,2,3-triazol-4-yl)-butanoyl-glycyl-prolyl-arginyl)-7-amino-4-methylenecoumarin- $] \cdot 2 \mathrm{HCl}$ (2b):

Using the experimental procedure as described vide supra utilizing substrate $\mathbf{2 b}$.
The following solution was prepared and stored at the indicated temperature:
Substrate: c(-Gly-Pro-Arg-AMC-[triazole]-spacer-) (2b, $1.4 \mathrm{mg}, 0.025 \mathrm{mmol}$ ) was dissolved in 0.25 mL BSA60 ${ }^{+}$buffer ( $60 \mathrm{mg} / \mathrm{mL}$ containing $\mathrm{NaCl}(8.18 \mathrm{mg} / \mathrm{mL})$ ) to give a 100 mM stock solution. From this stock solution a series of dilutions was prepared (total volume of $500 \mu \mathrm{~L}$ ) to give final substrate concentrations in the well of $0,50,100,200,400,600,800$ and $1000 \mu \mathrm{M}$. The dilutions are kept at $37^{\circ} \mathrm{C}$.

In brief, kinetic parameters were determined by monitoring the fluorescence increase in time as a result of the hydrolysis of the arginine-coumarin bond. The fluorescent counts were subsequently converted to AMC concentrations using a calibration curve. Plotting of the calculated AMC concentration versus time gave curves as depicted in Graph S1. While complete substrate consumption was observed after approximately 3 minutes for the linear Gly-Pro-Arg peptide, complete substrate consumption for the cyclic Gly-Pro-Arg peptide required more than 10 minutes. For both the linear and cyclic peptide the curves obtained at different substrate concentrations did not allow linear regression processing so that the initial rate constants were determined via non-linear regression by fitting of the data to a $6^{\text {th }}$ order polynomial. From these polynomials the initial rate constants were determined.

Graph S1 Normalized plots of the hydrolysis of the linear and cyclic peptide at a substrate concentration of $600 \mu \mathrm{M}$ where $(\Delta)=$ linear peptide (1), conc. Flla $=1.11 \mu \mathrm{M}$ and $(\stackrel{)}{ }$ ) = cyclic peptide (2b), conc. Flla $=0.45 \mu \mathrm{M}$

Subsequently applying the Michaelis-Menten equation on the obtained rate constants for linear peptide 1, we found a poor overlap of the fitted data with the experimental data which hampered accurate determination of the kinetic parameters. To assess the kinetic constants more accurately, a Lineweaver-Burk plot was constructed by plotting the reciprocal substrate concentrations against the reciprocal rate constants. The slope of the obtained linear line equals $k_{\text {cat }}$ and from the $x$-intercept, the $K_{M}$ could be determined $\left(x=-1 / K_{M}\right)$. Statistical analysis showed a tolerable $R^{2}$ of 0.97 . From calculations a $\mathrm{K}_{\mathrm{M}}$ value of $746.9 \mu \mathrm{M}$ and a $\mathrm{k}_{\text {cat }}$ of $29.3 \mathrm{~s}^{-1}$ were obtained for the linear peptide 1 (Table S2, entry 1). Utilizing the Michaelis-Menten equation on the initial rate constants obtained for compound $\mathbf{2 b}$, gave a good overlap of the fitted and experimental data, resulting in a $\mathrm{k}_{\mathrm{cat}}=23.3 \mathrm{~s}^{-1}$, and $\mathrm{a} \mathrm{K}_{\mathrm{M}}=3693.9 \mu \mathrm{M}$ (Table S2, entry 2).
