

### Supporting information

**rac-1,2-fc(BMes<sub>2</sub>)Br (2):** To a solution of 1,1'-dibromoferrocene (1.09 g, 3.16 mmol) in thf (18 mL) at -78°C was added *n*BuLi (1.98 mL of a 1.6M solution in hexanes, 3.16 mmol). After 30 min. tetramethylpiperidine (0.533 mL, 3.16 mmol) was added and the resulting mixture allowed to warm to -40°C. The temperature of the reaction was then *carefully* maintained between -40 and -30°C for 2 h. After this time, the reaction was again cooled to -78°C and FBMe<sub>2</sub> (1.13 g, 4.21 mmol, 90% purity as received from Sigma Aldrich) added as a solution in tetrahydrofuran (10 mL); the reaction mixture was allowed slowly to warm to 20°C and stirred for a further 15 h. The resulting red solution was diluted with ether (100 mL) and washed with water (50 mL) and brine (50 mL), before being dried *in vacuo* yielding the crude product as a dark red solid. Purification using column chromatography (hexane to 10% ethyl acetate/hexane) yielded **2** as a dark red amorphous solid. Yield: (1.225 g, 76%. Single crystals suitable for X-ray analysis were obtained by slow evaporation of a concentrated solution in diethyl ether. The ten largest q peaks are scattered across the asymmetric unit, with the largest peak being located ca. 1.14 Å from H173. The largest trough is located approximately in the centre of the phenyl group defined by C48, C49, C51, C52, C54 and C55. The residual peaks and troughs are probably due to poor data quality resulting e.g. from a damaged crystal, unresolved twinning etc. (i.e. from the poor quality of the crystal) Attempts to model these peaks were made, but without success. Despite the issues outlined above it seems unlikely that the overall connectivity of **2** is incorrect (especially given the reliability of the spectroscopic data), and no attempt is made to discuss the metrics obtained from the structure.
