## Experimental Section

**Materials and Measurements.** All reagents and solvents were used as received from commercial suppliers without further purification. TGA (thermal gravimetric analysis) was performed under a nitrogen atmosphere with a heating rate of 3 °C/min using a Shimadzu TGA-50 thermogravimetric analyzer. Powder X-ray diffraction (XRD) data were collected on a RIGAMU D/MAX 2550/PC X diffractometer with CuK $\alpha$  radiation. Analyses for C, H and N were carried out on a Flash EA1112 analyzer. N<sub>2</sub>, H<sub>2</sub>, C<sub>2</sub>H<sub>2</sub>, CH<sub>4</sub> and CO<sub>2</sub> adsorption isotherms were measured on ASAP 2020. A Coulter Omnisorp 100cx analyzer was used to measure methanol, ethanol, propanol, isopropanol sorption isotherm for activated **1a** formed by heating of the as-synthesized MOF **1a** at the temperature of 150 °C under high vacuum overnight. Fourier-transform (FT-IR) spectra (4000-650 cm<sup>-1</sup>) were measured with a Bruker Equinox 55 FTIR spectrometer on KBr disks.

**Fluorescence Measurements.** The fluorescence properties of MOF **1** and solvent included MOF **1a** were investigated in the solid state at room temperature. A fresh sample (30mg) of MOF **1** was activated and then immersed into methanol solvent (20 mL) with different organic solvent (0.2

mL) to form solvent included MOF **1a** which was collected by filtration and drying for 24 hrs at 20 °C. The sample was pressed on a glass slide for the photoluminescence studies. The photoluminescence (PL) spectra were recorded by a Hitachi F4500 fluorescence spectrometer. The photomultiplier tube voltage was 700 V and the scan speed was 240 nm/min, and the slit widths were 1.0 and 2.5 nm, respectively, for excitation and emission spectra.

**Derivation of the Isosteric Heats of Adsorption:** A virial type expression of the following form was used to fit the combined isotherm data for a given material at 295.0 and 273.2 K.<sup>1</sup>

$$\ln P = \ln N + 1/T \sum_{i=0}^m a_i N^i + \sum_{i=0}^n b_i N^i \quad (1).$$

Here,  $P$  is the pressure expressed in Torr,  $N$  is the amount adsorbed in mmol/g,  $T$  is the temperature in K,  $a_i$  and  $b_i$  are virial coefficients, and  $m, n$  represents the number of coefficients required to adequately describe the isotherms. The equation was fit using the statistical software package **SPSS** 16.0.  $m$  and  $n$  were gradually increased until the contribution of extra added  $a$  and  $b$  coefficients was deemed to be statistically insignificant towards the overall fit, as determined using the average value of the squared deviations from the experimental values was minimized. In all cases,  $m \leq 6$  and  $n \leq 3$ . The values of the virial coefficients  $a_0$  through  $a_m$  were then used to calculate the isosteric heat of adsorption using the following expression.

$$Q_{st} = -R \sum_{i=0}^m a_i N^i \quad (2).$$

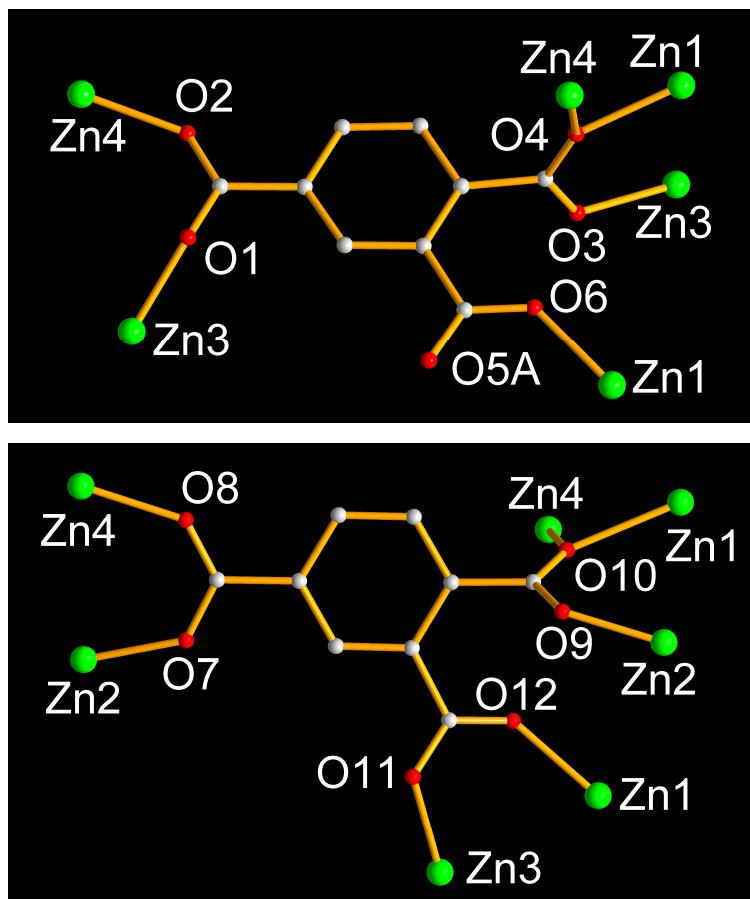

Here,  $Q_{st}$  is the coverage-dependent isosteric heat of adsorption and  $R$  is the universal gas constant of 8.3147 J K<sup>-1</sup> mol<sup>-1</sup>.

From these results, the Henry's constant ( $K_H$ ) is calculated from where  $T$  is temperature.<sup>2</sup>

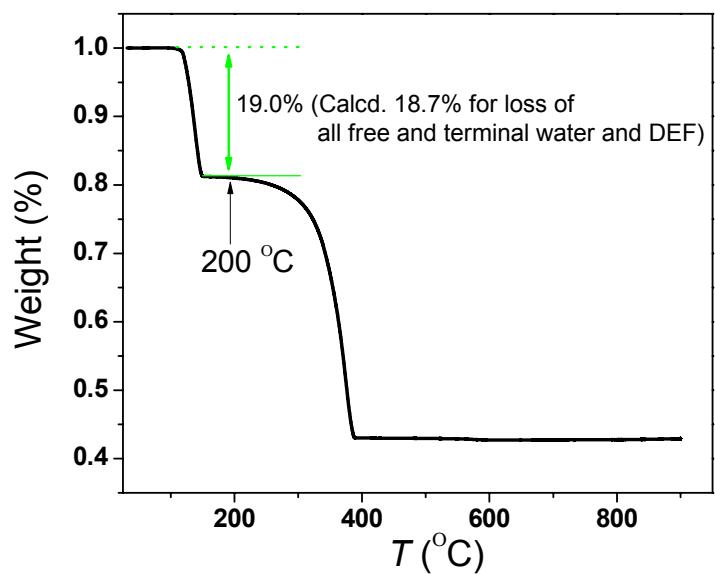

$$K_H = \exp(-b_0) \cdot \exp(-a_0/T)$$

The Henry's Law selectivity for gas component  $i$  over  $j$  at 295 K is calculated based on equation:

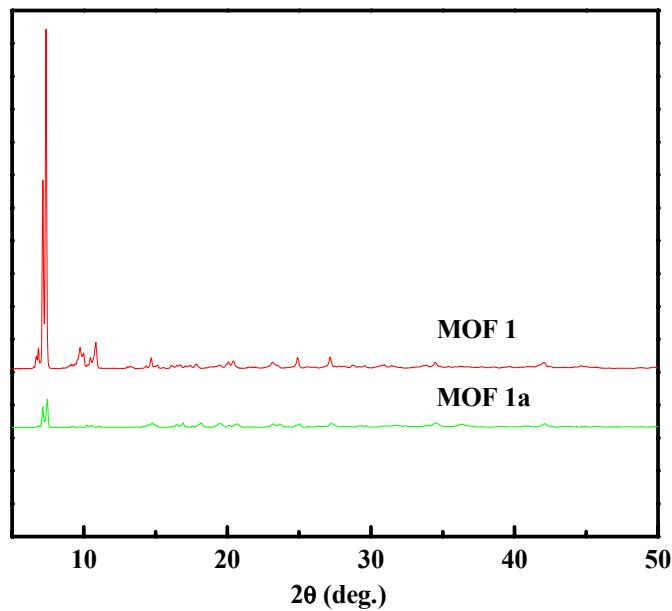

$$S_{ij} = K_{Hi} / K_{Hj}$$
