## **Experimental Section**

**Synthesis of TiO<sub>2</sub>(B)-t nanowires:** Potassium titanate nanowires (K-TNWs) were prepared by hydrothermal reaction of P25 in KOH solution. Typically, P25 (2g) was dispersed in KOH solution (80mL, 10M) and placed into a 100mL Teflon-lined autoclave. The autoclave was heated at 200°C for 24 h, after naturally cooled to room temperature, the produced white precipitates were isolated from solution by centrifugation and subsequently washed with deionized water and ion-exchange in 0.1M nitric acid solution for several times. The obtained proton exchanged titanate nanowires (H/K-TNWs) were washed with deionized water to pH 7 of the solution and then dried at 60°C in vacuum for 10 h. The TiO<sub>2</sub>(B)-t nanowires (t denotes the hydrothermal temperature) were prepared by adding H/K-TNWs (0.3 g) in nitric acid solution (40 mL, 0.1M) and placed into a 50 mL Teflon-lined autoclave. The autoclave was heated at the designed temperature (120, 150 and 180°C) for 24 h. After naturally cooled to room temperature, the obtained white TiO<sub>2</sub>(B) precipitations were isolated from solution by centrifugation and subsequently washed with deionized water and then dried at 60°C in vacuum for 10 h.

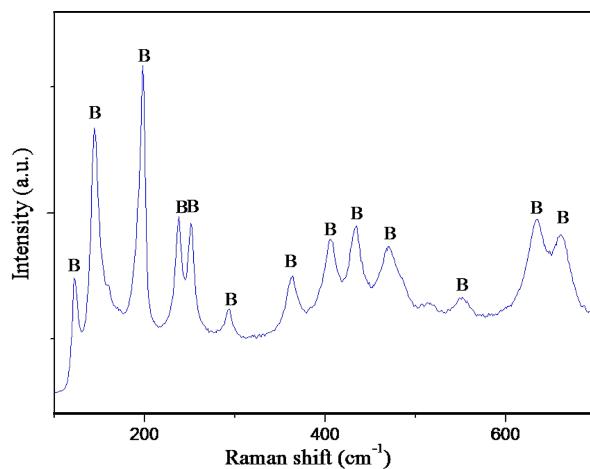

**Synthesis of TiO<sub>2</sub>(B)-c nanowires:** Sodium titanate nanowires (Na-TNWs) were prepared by reacting P25 (2g) with NaOH (10M) at 200°C for 24h, after naturally cooled to room temperature, the produced white precipitates were isolated from solution by centrifugation and subsequently washed with deionized water and ion-exchange in 0.01M nitric acid solution for several times. The obtained proton exchanged titanate nanowires H-TNWs were washed with deionized water to pH 7 of the solution and then dried at 60°C in vacuum for 10 h. The TiO<sub>2</sub>(B)-c nanowires were prepared by heating the H-TNWs at 450°C for 3 h in air.

**Materials Characterization:** The morphologies and the structures of the samples were characterized by scanning electron microscopy (SEM, S4800), Energy dispersive X-ray spectroscopy (EDS), transmission electron microscopy (TEM) and high-resolution TEM (HRTEM, FEI Tecnai F30, 300 kV), X-ray powder diffraction (XRD, Rigaku D/max-2500 diffractometer with CuK $\alpha$  radiation,  $\lambda=0.1542$ , 40 kV, 100 mA), Raman spectra of was measured on a Renishaw Invia Microraman Spectrometer III-001, the excitation source was He-Ne laser (633 nm), and BET (Micrometrics ASAP 2010).

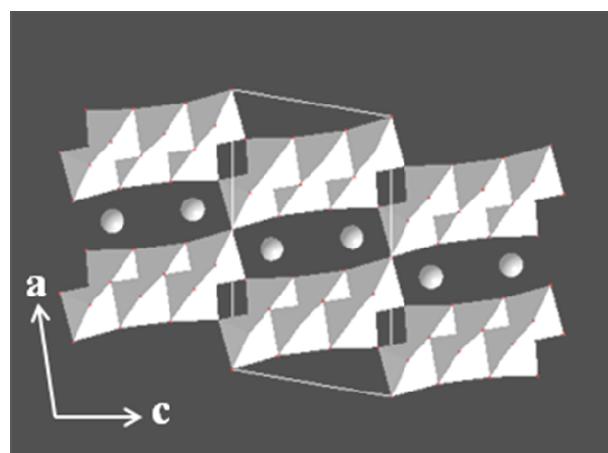

**Electrochemical measurement:** Lithium sheet was used as counter electrodes, composite materials comprising active mass (73 wt.%), carbonaceous additive (acetylene black, 15 wt.%) and poly(vinylidene difluoride) (PVDF, 12 wt.%) binder were used as the working electrode, and 1M LiPF<sub>6</sub> solution in a 1:1 (volume) mixture of ethylene carbonate (EC) and dimethyl carbonate (DMC) was used as electrolyte. The galvanostatic cycling was measured on a LAND cell test (Land-CT 2001C) system at a constant at the designed current density in the voltage range from 1.0V to 3.0V versus Li/Li<sup>+</sup>.
