## 1 Experimental Part

### 1.1 Materials

D,L-homocysteine thiolactone hydrochloride (HCTL·HCl, 99%, ABCR), glycerol carbonate chloroformate, N,N-diisopropylethylamine (DIPEA, 99%, ABCR), hexyl amine (99%, Sigma Aldrich), methyl acrylate (MA, 99%, Sigma Aldrich), triethylamine ( $\geq$ 99%, Sigma Aldrich), 3-(dimethylamino)-1-propylamine (99%, Acros Organics),  $\alpha$ -bromoisobutyryl bromide (98%, Sigma Aldrich) were used without further purification. Unless otherwise indicated, all solvents were purchased from commercial sources and were used without further purification. All reactions were performed under an Argon atmosphere, unless otherwise noted. Argon (Linde) was passed over molecular sieves (4 Å) and finely dispersed potassium on aluminum oxide before use.

### 1.2 Measurements

$^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded on a Bruker DPX-400 FT NMR spectrometer (400 MHz and 100 MHz, respectively) and are reported as follows: chemical shift  $\delta$  (ppm) (multiplicity, coupling constant  $J$  (Hz), number of protons, assignment). Dimethylsulfoxide (DMSO,  $\delta_{\text{H}} = 2.50$  ppm,  $\delta_{\text{C}} = 39.5$  ppm) was used as an internal standard. Chemical shifts are reported in ppm to the nearest 0.01 ppm for  $^1\text{H}$  and the nearest 0.1 ppm for  $^{13}\text{C}$ .

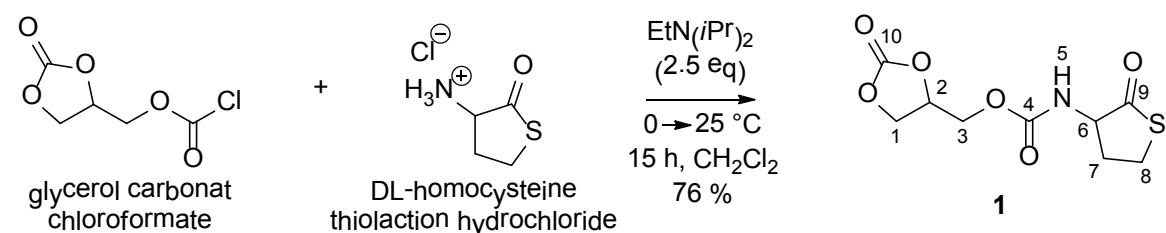

Infrared spectra were carried out on a ThermoNicolet FT-IR Nexus spectrometer and are recorded between KBr disks or using an ATR unit (ThermoNicolet, Smart SplitPEA). Transmission maxima are reported in wavenumbers ( $\text{cm}^{-1}$ ) and only selected intensities are reported.

Mass spectra were recorded on a Finnigan SSQ 7000 spectrometer and HRMS spectra on a Thermo Scientific LTQ Orbitrap XL spectrometer.

Differential scanning calorimetry (DSC) analysis was performed on a Netzsch DSC 204 ‘Phoenix’ (Netzsch, Selb, Germany) under nitrogen atmosphere using a scan rate of  $10 \text{ K}\cdot\text{min}^{-1}$ . For mp the inflection point was selected.

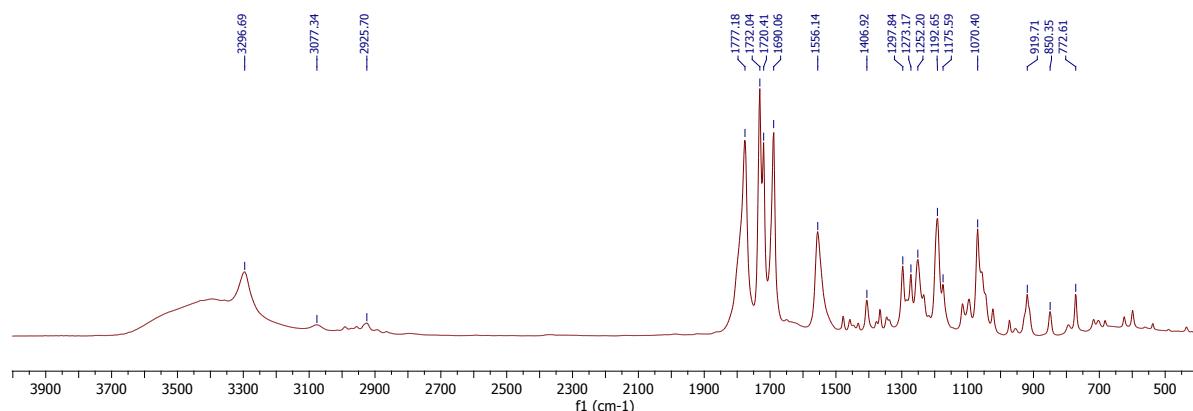

### 1.3 Syntheses

#### 1.3.1 Synthesis of the coupler (1)

To a stirred suspension of DL-homocysteine thiolactone hydrochloride (5 g, 32.5 mmol) and glycerol carbonate chloroformate (5.876 g, 32.5 mmol) in  $\text{CH}_2\text{Cl}_2$  (40 mL) at  $0^\circ\text{C}$  was added slowly (8 mL/h) ethyl-diisopropylamine (14 mL, 81.4 mmol). The reaction mixture was allowed to warm slowly to room temperature and stirred at room temperature for 15 h. The organic layer was washed with 1M  $\text{HCl}_{(\text{aq})}$  ( $2 \times 20 \text{ mL}$ ). Then, the aqueous layer was extracted with  $\text{CH}_2\text{Cl}_2$  ( $5 \times 15 \text{ mL}$ ). The combined organic layers were dried ( $\text{MgSO}_4$ ), the solvent was evaporated under reduced pressure to give the crude product. Purification by flash column chromatography on silica gel with EtOAc-DCM (3:1) as eluent, gave the urethane **1** (6.411, 76%) as a

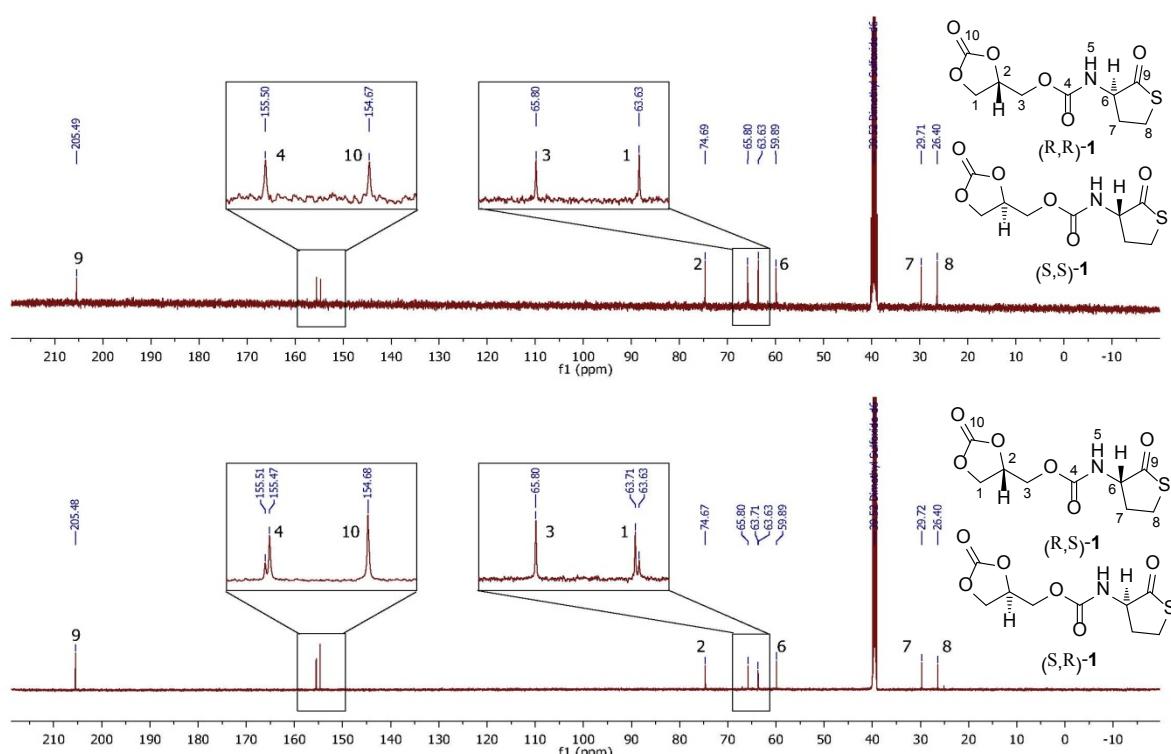

colorless oil. Mp 162.8 °C;  $^1\text{H}$  NMR (400 MHz, DMSO)  $\delta$  = 7.80 (d,  $J$  = 8.6 Hz, 1H, H5), 5.14 – 4.90 (m, 1H, H2), 4.57 (td,  $J$  = 8.6, 2.6 Hz, 1H, H3), 4.43 – 4.32 (m, 1H, H6), 4.31 – 4.17 (m, 3H, H1 and H3), 3.45 – 3.36 (m, 1H, H8), 3.26 (dd,  $J$  = 10.6, 6.8 Hz, 1H, H8), 2.46 – 2.37 (m, 1H, H7), 2.18 – 2.03 (m, 1H, H7).  $^{13}\text{C}$  NMR (101 MHz, DMSO)  $\delta$  = 205.5 (C9), 155.5 (C4), 154.7 (C10), 74.7 (C2), 65.8 (C3), 63.6 (C1), 59.9 (C6), 29.7 (C7), 26.4 (C8). IR (KBr) 3297 (NH), 3077, 2926, 1777 ( $\text{O}_2\text{C}=\text{O}$ ), 1732 (CONH), 1720, 1690 (COS), 1556, 1407, 1298, 1273, 1252, 1193, 1176, 1070, 920, 850, 773  $\text{cm}^{-1}$ . HRMS (ESI)  $m/z$  for  $\text{C}_9\text{H}_{11}\text{NO}_6\text{S}$  ( $\text{M} + \text{H}$ )<sup>+</sup> 262.0370, ( $\text{M} + \text{Na}$ )<sup>+</sup> 284.0188.

**Fig. S1** FTIR spectrum of multifunctional coupler **1**.

The precipitate, which occurred after the reaction time, was assumed to be ethyl-diisopropylamine hydrochloride. Therefore, it was initially included into the workup. Later by filtration it was investigated separately and turned out to be a mixture of remaining ethyl-diisopropylamine hydrochloride and the RR/SS diastereomer. The partially precipitated but pure RR/SS diastereomer **1** was obtained washing this mixture with  $\text{CH}_2\text{Cl}_2$  and 1M  $\text{HCl}_{(\text{aq})}$ . The RS/SR diastereomers could be accumulated via flash column chromatography.

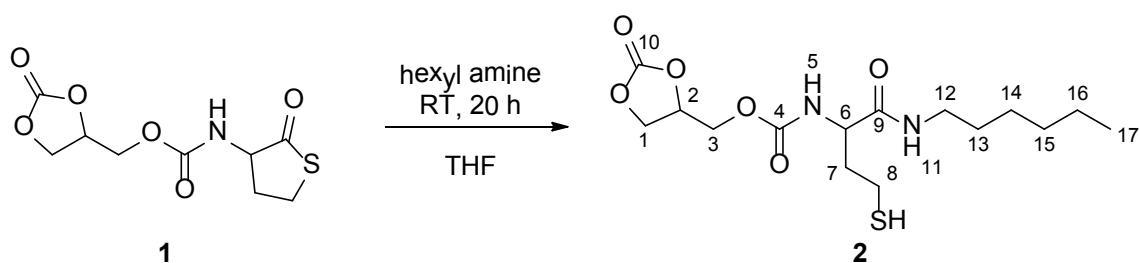

$^{13}\text{C}$  NMR spectra were recorded of both diastereomers (RS/SR and RR/SS) to trace subtle differences. Different chemical shifts could be observed for signal 4 and 1.

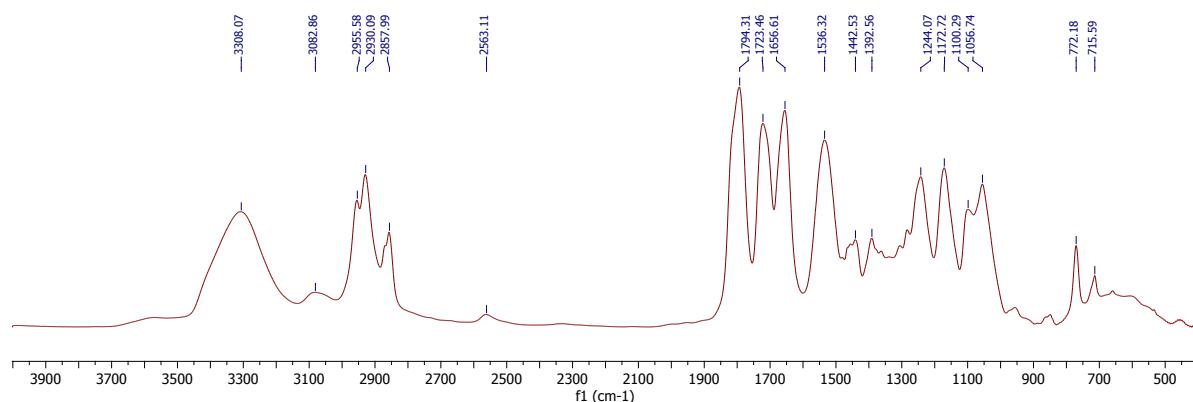

**Fig. S2** Comparison of the  $^{13}\text{C}$  NMR spectra of the RR/SS- (up) and the RS/SR diastereomers (down).

The RR/SS diastereomers shows the urethane carbon at  $\delta = 155.51$  ppm, whereas the same signal for the RS/SR diastereomers appears at  $\delta = 155.47$  ppm. The methylene carbon 1 of the RR/SS diastereomers can be found at  $\delta = 63.63$  ppm. For the RS/SR diastereomers this signal is shifted to  $\delta = 63.71$  ppm. Since the spectra of the RS/SR diastereomers is not entirely pure, a small peak of the RR/SS diastereomers can be observed, which allows the distinction of both mixtures of enantiomers.

Then, 3-(Dimethylamino)-propylamine ( $362 \mu\text{L}$ ,  $2.9 \text{ mmol}$ ) was added and the reaction mixture was stirred at  $70^\circ\text{C}$  for  $24 \text{ h}$ . Next, methyl acrylate ( $1.3 \text{ mL}$ ,  $14.4 \text{ mmol}$ ) and  $\text{Et}_3\text{N}$  ( $4 \mu\text{L}$ ,  $0.029 \text{ mmol}$ ) were added and the reaction mixture was stirred at room temperature for  $24 \text{ h}$ . The solvent and excess of methyl acrylate were evaporated under reduced pressure to give the crude alcohol (**5a/b**), which contained an 82:18 mixture of isomeric alcohols **5a** and **5b** (by  $^1\text{H}$  NMR spectroscopy). Finally,  $\alpha$ -bromo isobutyryl bromide ( $0.76 \text{ mL}$ ,  $3.7 \text{ mmol}$ ) was

added to a stirred solution of **5a/b** in CH<sub>2</sub>Cl<sub>2</sub> (10 mL) at 60 °C. The reaction mixture was stirred for 24 h at 60 °C. Then, 1 M NaOH<sub>(aq)</sub> (20 mL) was added and the solution stirred for 10 minutes. The layers were separated. The organic layer was washed with 1 M NaOH<sub>(aq)</sub> (2 × 20 mL). The aqueous layer was extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 × 10 mL). All combined organic layers were dried (MgSO<sub>4</sub>) and evaporated under reduced pressure to give the crude product. Purification by flash column chromatography on aluminum oxide with CH<sub>2</sub>Cl<sub>2</sub>-MeOH (10:0 → 9.8:0.2) as eluent gave the fully functionalized coupler (772 mg, 38%) as a light brown oil.

## 2 Crystallographic information for the RR/SS diastereomer of 1

Suitable crystals for single crystal X-ray diffraction were obtained by recrystallization from 2-butanone as colorless prisms. Intensity data were collected at 100 K on a Bruker D8 goniometer with a Bruker SMART APEX CCD detector in  $\omega$ -scan mode using Mo-K $\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ) from an Incoatec microsource with multi layer optics. Temperature was controlled with an Oxford Cryostream 700. Data were processed with SAINT<sup>1</sup> and multi scan absorption corrections were applied with SADABS<sup>2</sup>.

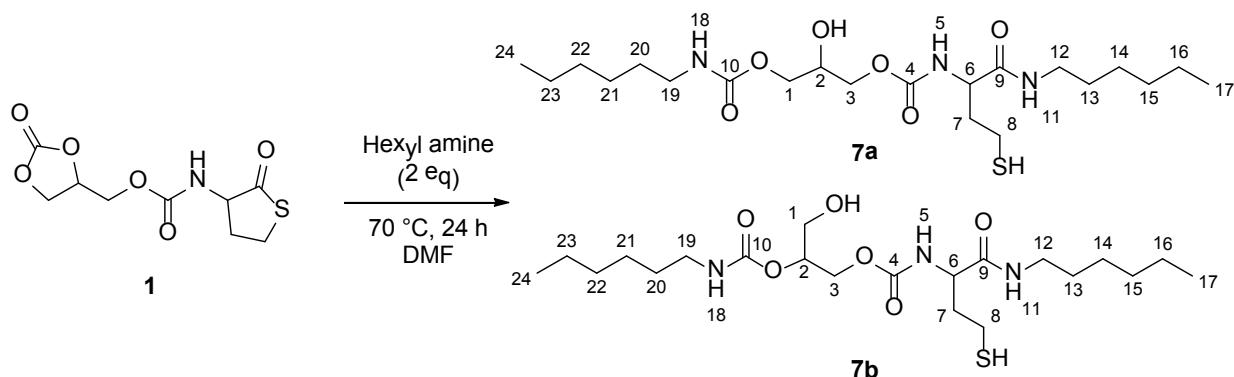

The structure was solved by direct methods using SHELXS97<sup>3</sup> and refined on  $F^2$  with SHELXL97<sup>3</sup>. Non-H atoms were refined with anisotropic displacement parameters. The amino-H was found in difference fourier map and refined freely with  $U_{iso}(\text{H}) = 1.2 U_{eq}(\text{N})$ ; all other hydrogen atoms were placed in idealized positions with  $U_{iso}(\text{H}) = 1.2 U_{eq}(\text{C})$ . Supplementary crystallographic data can be obtained free of charge from the Cambridge Crystallographic Data Centre via [http://www.ccdc.cam.ac.uk/data\\_request/cif](http://www.ccdc.cam.ac.uk/data_request/cif) (CCDC 919540).

### 3 NMR Analysis of the isomers

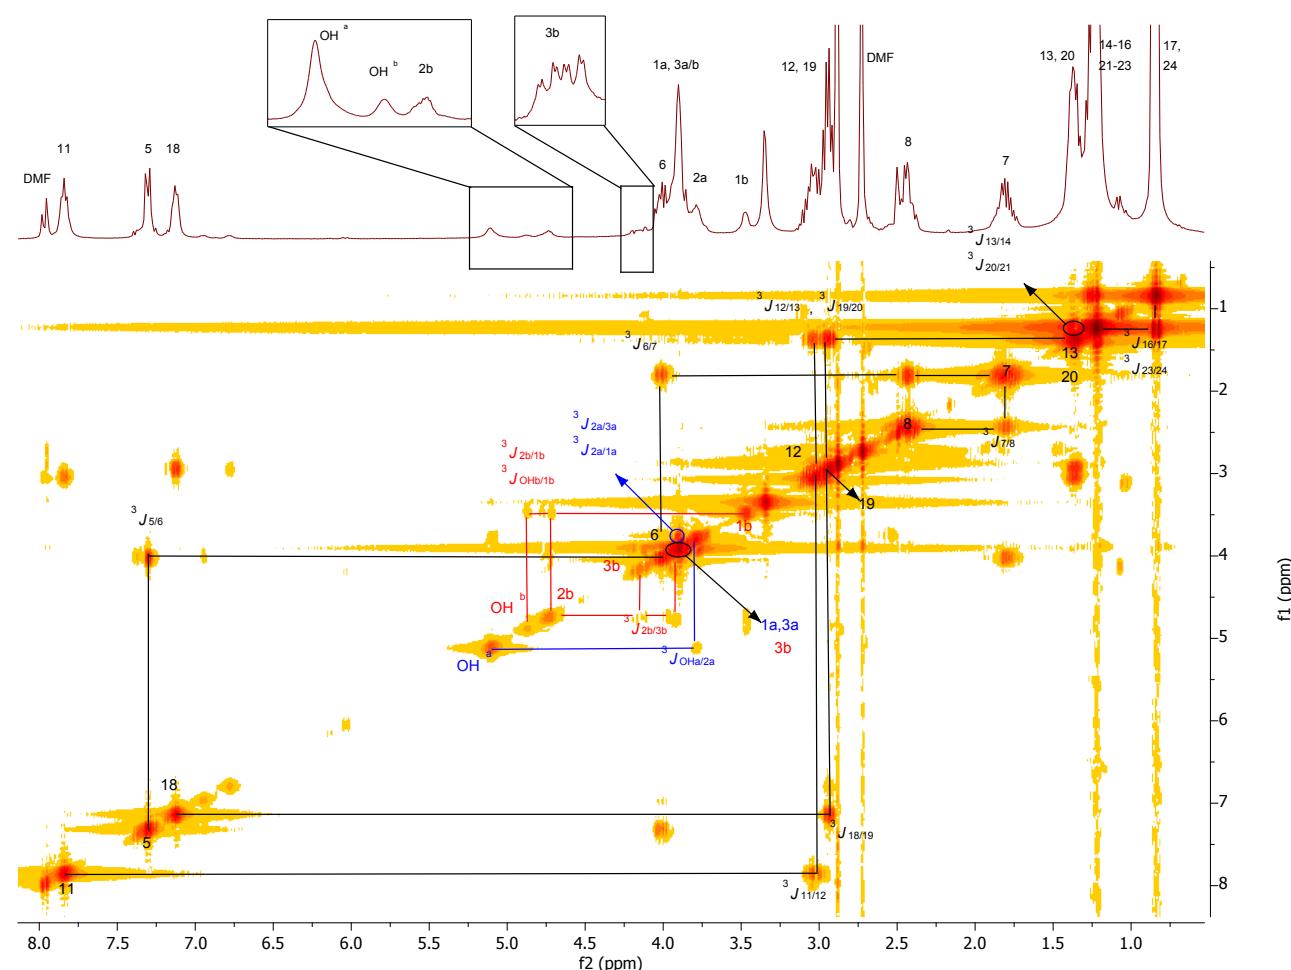

To analyze the coupling patterns of the isomers formed by the reaction of the second amine and the ethylene carbonate ring, the coupler was converted with 2.0 equivalents of hexyl amine at 70 °C (Scheme 1):

**Scheme 1.** Reaction of the coupler with 2.0 equivalents of hexyl amine.

The  $^1\text{H}$  NMR data show that both isomers bear different chemical shifts for the protons 1, 2 and 3. To start with the alkyl chains, protons 17 and 24 can be found as a triplet at  $\delta = 0.85$  ppm. Methylenes 14 to 16 and 21 to 23 appear at  $\delta = 1.23$  ppm. Protons 13 and 20 show a broad singlet at  $\delta = 1.38$  ppm. The multiplet at  $\delta = 1.94 - 1.67$  ppm shows methylene group 7, whereas the methylene group adjacent to the thiol (8) overlaps with the DMSO signal at  $\delta = 2.54 - 2.37$  ppm. Both  $\text{CH}_2$  groups next to the NH groups can be observed as a multiplet at  $\delta = 3.12 - 2.90$  ppm. The amide and urethane protons 11 and 18 can each be assigned to a broad triplet at  $\delta = 7.84$  and  $7.13$  ppm, respectively. Urethane proton 5 appears as a doublet at  $\delta = 7.30$  ppm with a  $^3J$  coupling value of 7.1 Hz. The adjacent proton at the stereocentre (6) is shifted to  $\delta = 4.07 - 3.96$  ppm. The alcohol group of isomer 7a can be found at  $\delta = 5.11$  ppm, whereas  $\text{OH}^\text{b}$  is shifted to higher field ( $\delta = 4.88$  ppm).

Methine protons 2a and 2b can be observed at  $\delta = 3.79$  and  $4.74$  ppm, respectively. 1b shows a broad triplet at  $\delta = 3.48$  ppm. Methylene group 1a is overlapping with methylene group 3a at  $\delta = 3.99 - 3.83$  ppm. The signal of 3b is splitting up and shows two multiplets. The first is located at  $\delta = 4.25 - 4.07$  ppm, the second overlaps with protons 3a and 1a at  $\delta = 3.99 - 3.83$  ppm. The complex coupling interactions between the nuclei of each isomer could be resolved by  $^1\text{H}, ^1\text{H}$ -COSY measurements (Figure S7).
