## General Experimental Conditions

All non-aqueous reactions were run under an inert atmosphere (argon or nitrogen) with flame-dried or oven-dried glassware using standard techniques. Anhydrous solvents were obtained by filtration through drying columns or obtained from commercial suppliers and used without further purification (THF, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, toluene, DMF).
Flash column chromatography was performed using 230-400 mesh silica, 70-290 mesh basic alumina modified to activity IV or ISCO Flash Silica cartridges with the indicated solvent system according to standard techniques. Analytical thin-layer chromatography (TLC) was performed on precoated, glass-backed silica gel plates. Visualization of the developed chromatogram was performed by UV absorbance ( 254 nm ), or aqueous potassium permanganate stain.
Infrared spectra (FTIR) were recorded in reciprocal centimeters $\left(\mathrm{cm}^{-1}\right)$.
Nuclear magnetic resonance spectra were recorded on a 400 MHz spectrometer. Chemical shifts for ${ }^{1} \mathrm{H}$ NMR spectra are recorded in parts per million from tetramethylsilane with the solvent resonance as the internal standard (chloroform, $\delta=7.27 \mathrm{ppm}$ ) or using chloroform with $1 \%$ tetramethylsilane as the internal standard. Data is reported as follows: chemical shift [integration, multiplicity ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{qn}=$ quintet, $\mathrm{m}=$ multiplet and $\mathrm{br}=$ broad), coupling constant in Hz$].{ }^{13} \mathrm{C}$ NMR spectra were recorded with complete proton decoupling. Chemical shifts are reported in parts per million from tetramethylsilane with the solvent resonance as the internal standard ( ${ }^{13} \mathrm{CDCl}_{3}: 77.0 \mathrm{ppm}$ ) or using chloroform with $1 \%$ tetramethylsilane as the internal standard.
Assignments of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ spectra were made by the analysis of $\delta / J$ values and COSY, HSQC and HMBC experiments as appropriate.
Melting points are uncorrected.
Reagents: Commercial reagents were used as supplied or purified by standard techniques where necessary.

## Compound Handling/Purification/Storage:

All synthetic intermediates were stored under argon at $-20^{\circ} \mathrm{C}$ for short periods. Oxetanes 1a-d were bench stable; oxetane 1a was stored at rt for 3 months without degradation.
Where required for purification, the activity of basic alumina was altered by the addition of water to commercial basic alumina (activity I) and evenly distributed (activity IV: $10 \% \mathrm{w} / \mathrm{w}$ water). ${ }^{1}$

## Preparation of a 0.61 M solution of LiHMDS.

A solution of HMDS ( $0.14 \mathrm{ml}, 0.67 \mathrm{mmol}$ ) in THF ( 0.48 mL ) was cooled to $-78^{\circ} \mathrm{C}$ for 5 min then $n$ BuLi ( $0.38 \mathrm{~mL}, 0.61 \mathrm{mmol}, 1.6 \mathrm{M}$ in hexane) was added dropwise. Solution stirred at $-78^{\circ} \mathrm{C}$ for 30 min then warmed to $0^{\circ} \mathrm{C}$ for 30 min prior to use.

## Optimisation of Oxetane Formation

Initial investigations treated sulfone $\mathbf{4 a}(0.52 \mathrm{mmol})$ with base ( 2 equiv.) in THF at $0^{\circ} \mathrm{C}$ for 1 h then warmed to rt for 1 h (Table S1, entries 1-7). Amine bases were generally successful in promoting cyclisation, with LiHMDS the most effective, especially when freshly prepared (entries 7 and 8).

Table S1: Selected optimisation: intramolecular cyclisation of sulfone 4a to oxetane 1a.

${ }^{\text {a }}$ Conditions A , addition of the substrate to a solution of the base; Conditions B, addition of the base to a solution of the substrate. ${ }^{b}$ Yield determined by ${ }^{1} \mathrm{H}$ NMR with respect to $1,3,5$ trimethoxybenzene as an internal standard. ${ }^{\text {c }}$ Base made immediately prior to use. ${ }^{d}$ Reaction run at $-78^{\circ} \mathrm{C}$ as opposed to $0^{\circ} \mathrm{C}$. ${ }^{e}$ Reaction time of 1 h .

The order of addition of the base and substrate was examined next using LiHMDS and nBuLi as they were the two most effective bases under the original conditions adding a solution of tosyl sulfone 4a to a solution of base in THF. Reversing the addition, base added to sulfone, resulted in a marked increase in yield using LiHMDS to $89 \%$ by ${ }^{1} \mathrm{H}$ NMR (entries 8 and 10). Under these conditions the amount of LiHMDS could be reduced to 1.2 equiv affording a further increase in yield (entry 11). The concentration of the reaction was next investigated, maintaining relatively dilute conditions to favour intramolecular cyclisation. Increasing the concentration from 0.025 M to 0.05 M gave a notable reduction in yield (entry 12). More dilute conditions (entry 13) gave a marginal increase in yield and 0.025 M was chosen as optimal. The reaction time could be reduced to 1 h at $0^{\circ} \mathrm{C}$ (entry 14). Further reduction of the amount of base to 1.1 equiv gave the optimal reaction conditions (entry 15) which afforded a quantitative conversion to the oxetane product; decreasing the equivalents further resulted in a decrease in yield (entry 16).

Under these conditions, the synthesis was scaled up to 6.5 mmol to give 1.2 g oxetane $\mathbf{1 a}$ with a $93 \%$ isolated yield (Scheme 1).

Sodium hydride ( $60 \%$ in mineral oil, $0.79 \mathrm{~g}, 19.8 \mathrm{mmol}$ ) was added to a solution of 2mercaptopyridine $\mathbf{S 8}(2.0 \mathrm{~g}, 18.0 \mathrm{mmol})$ in DMF ( 50 mL ) at $-5^{\circ} \mathrm{C}$ and stirred for 10 min . A solution of chloroiodomethane ( $1.96 \mathrm{~mL}, 27 \mathrm{mmol}$ ) in DMF $(7 \mathrm{~mL})$ was added in one portion and stirred for 1 h 45 min at rt. The reaction was quenched by the addition of sat. aq. $\mathrm{NH}_{4} \mathrm{Cl}$ $(100 \mathrm{~mL})$ and diluted with EtOAc $(30 \mathrm{~mL})$ then extracted with EtOAc $(4 \times 40 \mathrm{~mL})$. ## Optimisation of Deprotonation of 1a for Reaction with Electrophiles

## With LiHMDS (Conditions A, Table 1)

Under the initial conditions oxetane 1a was treated with various bases at T1 for time 1 prior to the addition of Mel to form oxetane 5. The reaction was then warmed to T2 over time 2. Entries 1-4 in table S2 show that under these conditions LiHMDS was the best base affording a yield of $76 \%$. Warming to $0^{\circ} \mathrm{C}$ was required; quenching the reaction at $-78^{\circ} \mathrm{C}$ afforded a much lower yield (entry 5). Increasing the deprotonation time to 30 min did increase the yield to $84 \%$ (entry 6). The equivalents of LiHMDS employed were also investigated however it was found that increasing the equivalents to 1.3 and 1.5 did not affect the reaction yield. The addition of the substrate in THF to a solution of the base was favourable over the addition of the base to the substrate (entries 6 and 7). Finally we investigated the addition of Mel immediately after the addition of base. Pleasingly this increased the yield of the reaction with Mel to $90 \%$ (entry 8), and provided our optimised set of conditions A.

During the course of this work, Capriati and co-workers reported the deprotonation of 2-phenyloxetane with sBuLi. ${ }^{7}$ Consequently sBuLi was further examined to deprotonate the sulfonyl oxetane. A summary of the results is shown in Table S3.

${ }^{\text {a }}$ Conditions: base added to oxetane $1 \mathrm{a}(0.24 \mathrm{mmol})$, at $-78^{\circ} \mathrm{C}$ for time 1 ; Mel (2 equiv) added then warmed to temp 2 for time 2. ${ }^{b}$ Yield determined by ${ }^{1} \mathrm{H}$ NMR with respect to $1,3,5$ trimethoxybenzene as an internal standard.

The initial conditions employed 1.1 equivalents of $s B u L i$ followed by the addition of 2 equivalents of Mel after 5 min . (table S3, entry 1). Two products were obtained, the desired methylated oxetane 5 but also $1 \%$ of the double methylated oxetane 10, along with remaining 1a. Increasing the equivalents of $s B$ BLi employed from 1.1 to 1.2 and 1.4 increased the yield of the desired product however unreacted starting material and double methylated oxetane were also observed (table S3, entries 2 and 3 ). This implies that the second methylation occurs before all $1 \mathbf{a}$ is consumed. Increasing the deprotonation time (time 1) afforded an increase in formation of oxetane 10 (entry 4). Using 1.1 equiv base with the longer deprotonation did reduce the formation of 10 but decreased the yield of the desired oxetane 5 as well (entry 5). Warming the reaction to rt immediately after addition of Mel significantly increased the amount of oxetane 10 formed and decreased the yield of oxetane 5, however for the first time no unreacted starting material was observed (entry 6). The addition of Mel immediately after the addition of sBuLi was investigated (entry 7) but this was not an improvement on previous reaction conditions.

As a result we further investigated the use of $n \mathrm{BuLi}$ (entries 9-10), which displayed reduced formation of 10. The optimal yield of oxetane $\mathbf{5}$ was achieved using 1.3 equiv nBuLi which limited the amounts of starting material and double methylated product whilst improving the yield of desired product to $86 \%$ (entry 9 ). This provided the second set of optimised conditions (conditions B).

## Calculated fragment-like and lead-like properties of oxetanes 1a-d, 5-9 and 10-16

The scope of oxetanes prepared were analysed against parameters used to indicate desirable molecular properties, with particular reference to the Astex 'rule of 3' for fragments, and leadlikeness criteria recently proposed by Churcher and co-workers.

Criteria as defined by Congreve et al. for fragments. ${ }^{10}$

- cLogP < $3^{11}$
- Three or fewer H-bond donors (HBD)
- Three or fewer H-bond acceptors (HBA)
- MW < 300 daltons

Secondary criteria include: Number of rotatable bonds $($ NROT $) \leq 3$; Polar surface area (PSA) $\leq 60$.
Köster et al recently proposed six or fewer HBA to be a more appropriate guideline. ${ }^{12}$
Criteria as defined by Churcher et al. for lead-like compound: ${ }^{13}$

- $14 \leq$ heavy atoms $\leq 26(200 \leq$ Molecular weight $(M W) \leq 300 \mathrm{Da})$
- $-1 \leq \mathrm{cLog} \mathrm{P} \leq 3$
- more 3D shape/sp ${ }^{3}$ content favoured
