## 1. Chemistry

General. Column chromatography purifications were performed on Merck silica gel (40-63 $\mu \mathrm{m}$ ). Thin-layer chromatography (TLC) was carried out on Merck DC Kieselgel 60 F-254 aluminium sheets. Compounds were visualized by illumination with a short wavelength UV lamp $(\lambda=254 \mathrm{~nm})$. All solvents were dried following standard procedures $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CH}_{3} \mathrm{CN}\right.$ : distillation over $\mathrm{P}_{2} \mathrm{O}_{5}$, DMF: distillation over BaO under reduced pressure, THF: distillation over $\mathrm{Na} /$ benzophenone). Triethylamine was distilled from $\mathrm{CaH}_{2}$ and stored over BaO or KOH . ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker DPX 300 spectrometer (Bruker, Wissembourg, France). Chemical shifts are expressed in parts per million (ppm) from $\mathrm{CDCl}_{3}$ $\left(\delta_{\mathrm{H}}=7.26, \delta_{\mathrm{C}}=77.16\right), \mathrm{MeOD}\left(\delta_{\mathrm{H}}=3.31, \delta_{\mathrm{C}}=49.00\right)$ or DMSO ( $\left.\delta_{\mathrm{H}}=2.50, \delta_{\mathrm{C}}=39.52\right) .{ }^{1} \mathrm{~J}$ values are expressed in Hz. Residual solvents contained in NMR sample were indicated on spectra. Mass spectra were obtained with a Finnigan LCQ Advantage MAX (ion trap) apparatus equipped with an electrospray source. All analyses were performed in the positive mode.

All final oximes were confirmed to be $\geq 95 \%$ purity based on HPLC analysis. Analytical HPLC was performed on a Thermo Electron Surveyor instrument equipped with a PDA detector under the following conditions: Thermo Hypersil GOLD C18 column ( $5 \mu \mathrm{~m}, 4.6 \mathrm{x}$ 100 mm ) with MeOH and $0.1 \%$ aq. trifluoroacetic acid (TFA) as eluents $[0.1 \%$ aq. TFA/MeOH ( $90 / 10$ ) ( 5 min ), followed by linear gradient from $10 \%$ to $100 \%$ of $\mathrm{MeOH}(45$ min )] at a flow rate of $1.0 \mathrm{~mL} / \mathrm{min}$ and UV detection Max Plot 220-360 nm.

## 2. Biological assays

Inhibition of $\boldsymbol{h} \boldsymbol{A C h E}$ and $\boldsymbol{h B C h E}$ by OPNAs. Recombinant $h \mathrm{AChE}$ and $h \mathrm{BChE}$ were produced and purified as previously described. ${ }^{2,3}$ VX and tabun were from DGA maîtrise NRBC (Vert le Petit, France). Paraoxon-ethyl was purchased from Sigma-Aldrich. HI-6 was from Pharmacie Centrale des Armées (Orléans, France). All other chemicals including paraoxon were from Sigma. Stock solution of VX and tabun were 5 mM in isopropanol. The inhibition of $120 \mu \mathrm{M} h \mathrm{AChE}$ or $100 \mu \mathrm{M}$ of $h \mathrm{BChE}$ is realized with a 5-fold excess of OPNAs

[^1]and was performed in tris buffer ( $20 \mathrm{mM}, \mathrm{pH} 7.4,0.1 \% \mathrm{BSA}$ ) at $25^{\circ} \mathrm{C}$. After a 20 -minute incubation, inhibited $h \mathrm{AChE}$ or $h \mathrm{BChE}$ was desalted on PD-10 column (GE Healthcare).

Reactivation of $\boldsymbol{h} \mathbf{A C h E}$ and $\boldsymbol{h B C h E}$ inhibited by OPNAs. OPNA-inhibited $h \mathrm{AChE}$ was incubated at $37^{\circ} \mathrm{C}$ with different concentrations of oxime in 0.1 M phosphate buffer, pH 7.4 , $0.1 \%$ BSA, $5 \%$ methanol (See table below). Methanol was used for complete dissolution of the oximes. $50-\mu \mathrm{l}$ aliquots of mix was transferred to $1-\mathrm{mL}$ cuvettes at time intervals ranging from 1 to 10 minutes depending on the reactivation rate, for measurement of $h \mathrm{AChE}$ activity ( 1 mM acetylthiocholine) or $h \mathrm{BChE}$ activity ( 1 mM butyrylthiocholine), in Ellman's buffer (phosphate $0.1 \mathrm{M}, \mathrm{pH} 7.4,0.1 \% \mathrm{BSA}, 0.5 \mathrm{mM}$ DTNB, $25^{\circ} \mathrm{C}$ ). The increase in absorbance at 412 nm was followed on a Uvikon 943 spectrophotometer.

The enzyme activity in the control remained constant during the experiment. The percentage of reactivated enzyme ( $\% \mathrm{E}_{\text {react }}$ ) was calculated as the ratio of the recovered enzyme activity and activity in the control. The apparent reactivation rate $\mathrm{k}_{\text {obs }}$ for each oxime concentration, the dissociation constant $K_{\mathrm{D}}$ of inhibited enzyme-oxime complex (E-POx) and the maximal reactivation rate constant $k_{\mathrm{r}}$, were calculated by non-linear fit using the standard oxime concentration-dependent reactivation equation derived from the following scheme:

$$
\begin{gathered}
\mathrm{E}-\mathrm{P}+\mathrm{Ox} \underset{\mathrm{D}}{\stackrel{\mathrm{~K}_{\mathrm{D}}}{\rightleftarrows}} \mathrm{E}-\mathrm{POx} \xrightarrow[\mathrm{r}]{\stackrel{\mathrm{k}_{\mathrm{r}}}{\rightleftarrows}+\mathrm{POx}} \\
\% \mathrm{E}_{\text {react }}=100 \cdot\left(1-\mathrm{e}^{\mathrm{k}_{\mathrm{obs}} \cdot \mathrm{t}}\right) \quad \text { and } \quad \mathrm{k}_{\mathrm{obs}}=\frac{\mathrm{k}_{\mathrm{r}}[\mathrm{Ox}]}{\mathrm{K}_{\mathrm{D}}+[\mathrm{Ox}]}
\end{gathered}
$$

Concentration of oximes 2-4 $(\mu \mathrm{M})$ used to determine the concentration dependence of the reactivation rate $\mathrm{k}_{\mathrm{obs}}$ for reactivation of VX- $h \mathrm{BChE}$ and VX-, tabun- and paraoxon-inhibited $h \mathrm{AChE}$.
