#### Experimental Section

**Materials and methods.** 2-quinolinephosphonic acid was prepared according to the literature method<sup>1</sup> and all the other starting materials were obtained from commercial sources without further purification. Elemental analyses for C, H and N were determined with a Perkin Elmer 240C elemental analyzer. The Dy contents in the doped samples were analyzed using Inductively Coupled Plasma Optical Emission Spectrometry (ICP OES-Optima 5300DV, PE.). Infrared spectra were measured using KBr pellets on a Bruker Tensor 27 spectrometer in the range of 400-4000 cm<sup>-1</sup>. Thermogravimetric analysis (TGA) were performed on a Mettler-Toledo TGA/DSC STARE thermal analyzer in the range of 25-600°C under a nitrogen flow at a heating rate of 5°C/min. Powder X-ray diffraction (PXRD) data were recorded on a Bruker D8 ADVANCE X-ray powder diffractometer (Cu-K $\alpha$ ) over the 2 $\theta$  range of 5 to 50° at room temperature. The magnetic susceptibility data were recorded on a Quantum Design MPMS SQUID VSM system. The diamagnetic contribution of the sample itself was estimated from Pascal's constant.<sup>2</sup>

The crystal data were collected on a Bruker SMART APEX II diffractometer using monochromated Mo-K $\alpha$  radiation ( $\lambda$  = 0.71073 Å) at 296

K for  $\alpha$ -Dy,  $\beta$ -Dy and  $\beta$ -Y. The structures were solved by direct methods and refined on  $F^2$  by full matrix least squares using SHELXTL.<sup>3</sup> All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were either put in calculated positions or found from the difference Fourier maps and refined isotropically. Selected bond lengths and angles are given in Table S1.

**The Cole-Cole plot fitting method:** The  $ac$  magnetic susceptibilities can be described by the Cole-Cole plots using the generalized Debye model in Eq(S1), Eq(S2)<sup>4</sup> (single relaxation model) and/or a linear combination of two modified Debye models, as shown in Eq(S3) and Eq(S4)<sup>5</sup> (double relaxation model):

$$\chi'(\omega) = \chi_s + \frac{(\chi_T - \chi_s) \left[ 1 + (\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) \right]}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2(1-\alpha)}} \quad (S1)$$

$$\chi''(\omega) = \frac{(\chi_T - \chi_s) \left[ 1 + (\omega\tau)^{1-\alpha} \cos(\pi\alpha/2) \right]}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2(1-\alpha)}} \quad (S2)$$

$$\chi'(\omega) = \chi_s + (\chi_T - \chi_s) \left( \frac{f_A \left[ 1 + (\omega\tau_A)^{1-\alpha_A} \sin(\pi\alpha_A/2) \right]}{1 + 2(\omega\tau_A)^{1-\alpha_A} \sin(\pi\alpha_A/2) + (\omega\tau_A)^{2(1-\alpha_A)}} + \frac{(1-f_A) \left[ 1 + (\omega\tau_B)^{1-\alpha_B} \sin(\pi\alpha_B/2) \right]}{1 + 2(\omega\tau_B)^{1-\alpha_B} \sin(\pi\alpha_B/2) + (\omega\tau_B)^{2(1-\alpha_B)}} \right) \quad (S3)$$

$$\chi''(\omega) = (\chi_T - \chi_s) \left( \frac{f_A \left[ 1 + (\omega\tau_A)^{1-\alpha_A} \cos(\pi\alpha_A/2) \right]}{1 + 2(\omega\tau_A)^{1-\alpha_A} \sin(\pi\alpha_A/2) + (\omega\tau_A)^{2(1-\alpha_A)}} + \frac{(1-f_A) \left[ 1 + (\omega\tau_B)^{1-\alpha_B} \cos(\pi\alpha_B/2) \right]}{1 + 2(\omega\tau_B)^{1-\alpha_B} \sin(\pi\alpha_B/2) + (\omega\tau_B)^{2(1-\alpha_B)}} \right) \quad (S4)$$

where  $\chi_s$  is the adiabatic susceptibility,  $\chi_T$  is the isothermal susceptibility, and  $\tau$  is the average relaxation time of magnetization, and the  $\alpha$  parameter, which ranges between 0 and 1, quantifies the width of the  $\tau$  distribution,  $f_A$  represents the percentage of relaxation A.
