Fig. S1 The effect of the metal precursors. XRD of NPs prepared with: (A) $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{CuSO}_{4}$. ( B ) $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$. (C) $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{ac})_{2}$. (D) $\mathrm{H}_{2} \mathrm{PtCl}_{6}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$. The initial molar ratios are indicated next to the patterns. Blue vertical lines represent the fcc- Pt phase and purple vertical lines represent the fcc-Cu phase.

Two different molar ratios (7:3 and 1:1) of $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{CuSO}_{4}$ precursors were reacted at $197{ }^{\circ} \mathrm{C}$. The XRD analysis of the formed alloy is presented in Fig. S1A. The initial Pt:Cu ratio of 7:3, gives uniform peaks positioned between the Pt and Cu diffraction lines at $40.35^{\circ}$ and $46.6^{\circ}$. The lattice constant corresponding to the (111) peak position is $3.87 \AA$. The composition of the alloy as calculated by using Vegard's law is $84: 16 \mathrm{Pt}: \mathrm{Cu}$.

When the lower $\mathrm{Pt}: \mathrm{Cu}$ initial ratio (1:1) was used, the diffraction peaks still appeared between the Pt and Cu diffraction lines $\left(41.8^{\circ}\right.$ and $\left.47.9^{\circ}\right)$. However, the peak was not uniform, but rather tilted. This suggests that more than one alloy was formed, with different compositions. The TEM images obtained from these syntheses are presented in Fig. S2

Fig. S2 TEM images of PtCu NPs prepared with $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{CuSO}_{4}$ at different initial Pt :Cu molar ratios: (A) 7:3. (B) 1:1.

Fig. S1B shows $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ at 7:3 and 3:7 molar ratios after a reaction at $197{ }^{\circ} \mathrm{C}$. For both ratios a uniform alloy wasn't formed. In both XRD patterns there are several peaks positioned between the Pt and Cu diffraction lines. For the $7: 3$ initial ratio, one Pt-rich alloy peak is present next to the Pt diffraction line and one Cu peak is positioned on the Cu diffraction line. An alloy with intermediate composition between the Pt-rich alloy and the Cu was also formed, as indicated by the shoulder next to the Pt-rich peak, at higher $2 \theta$ values. The $3: 7$ initial ratio results in an XRD pattern with multiple peaks positioned between the Pt and Cu diffraction lines. The most pronounced peaks are of Pt-rich alloy positioned next to the Pt diffraction line, and a strong Cu peak. Between these two peaks, there are several low-intensity peaks, indicating several different PtCu alloys with various compositions. The TEM images the products (Fig. S3) show non-uniform shape and size distribution. In both samples, small spherical particles, as well as large faceted particles were formed. At the lower Pt:Cu ratio (3:7), large particles $(>50 \mathrm{~nm})$ can also be observed. These results are consistent with the multiple peaks in the XRD.

Fig. S3 TEM images of PtCu NPs prepared with $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ at different initial $\mathrm{Pt}: \mathrm{Cu}$ molar ratios: (A) 7:3. (B) 3:7.

Fig. S1C shows the XRD analysis of a synthesis using $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{ac})_{2}$ precursors at $197^{\circ} \mathrm{C}$. When the 7:3 Pt:Cu initial ratio was used, one pronounced non-uniform peak appeared next to the Pt diffraction line, indicating the formation of Pt-rich alloys. In addition, a Cu peak at low intensity is also observed. However, when 3:7 $\mathrm{Pt}: \mathrm{Cu}$ initial ratio was used, two non uniform peaks were formed. One is positioned next to the Pt diffraction line, indicating the formation of Pt-rich alloys. The second is positioned next to the Cu diffraction line, indicating the formation of Cu-rich alloys. In the TEM results (Fig. S4), non-uniform NPs are seen for both ratios. Small and large ( $>50 \mathrm{~nm}$ ) NPs are present in both samples. The TEM images support the XRD analysis, in which nonuniform compositions are present. Furthermore, there is a difference in the NP shape between the syntheses. At 7:3 Pt:Cu ratio the NPs are spherical and faceted, while at $3: 7 \mathrm{Pt}: \mathrm{Cu}$ ratio there is a mixture of faceted and concave NPs.

Fig. S4 TEM images of PtCu NPs prepared with $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{ac})_{2}$ at different initial $\mathrm{Pt}: C u$ molar ratios: (A) 7:3. (B) 3:7.

A $197{ }^{\circ} \mathrm{C}$ reaction of $\mathrm{H}_{2} \mathrm{PtCl}_{6}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ precursors at $3: 7$ and 7:3 initial molar ratios, resulted in uniform XRD peaks (Fig. S1D). For both ratios, the peaks are positioned between the Pt and Cu diffraction lines, indicating the formation of one uniform alloy. When 7:3 Pt:Cu initial ratio was used, the (111) and (200) peaks are positioned at $40.15^{\circ}$ and $46.85^{\circ}$, respectively. Using Bragg's law gives a lattice constant of $d_{111}=3.89 \AA$, which corresponds to $90: 10(\mathrm{Pt}: \mathrm{Cu})$. When $3: 7 \mathrm{Pt}: \mathrm{Cu}$ initial ratio is used, the (111) and (200) peaks appear at $40.2^{\circ}$ and $46.65^{\circ}$, respectively. These peaks are practically at the same position, meaning that the alloy's composition did not change due to the precursor ratio variation. The TEM images of both samples (Fig. S5) present non-uniform shape and at 7:3 $(\mathrm{Pt}: \mathrm{Cu})$ initial ratio, also non-uniform size.

Fig. 55 TEM images of $\mathrm{PtCu} N P s$ prepared with $\mathrm{H}_{2} \mathrm{PtCl}_{6}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ at different initial Pt:Cu molar ratios: (A) 7:3. (B) 3:7.

Fig. S6 Studying the effect of PVP concentration at $197^{\circ} \mathrm{C}$. XRD of NPs prepared with $3: 7$ initial molar ratios of $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$. The $[\mathrm{M}]:[P V P]$ ratios are indicated next to the patterns.

Fig. S7 Studying the evolution in time of PtCu NPs. XRD of NPs prepared with $3: 7$ initial molar ratio of $\mathrm{H}_{2} \mathrm{PtCl}_{6}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ at $180{ }^{\circ} \mathrm{C}$. Termination times are indicated next to the patterns.

Fig. $\mathbf{5 8}$ TEM images of pure metallic NPs. (A) Pt NPs prepared using Pt(acac) $)_{2}$ (B) Cu NPs prepared using Cu(acac) $)_{2}$.

Fig. S9 TEM image of the products obtained for reactions in which $\mathrm{Pt}(\mathrm{acac})_{2}$ and $\mathrm{Cu}(\mathrm{acac})_{2}$ were added at different stages. (A) Pt and Cu NPs were formed separately and then heated together at $180^{\circ} \mathrm{C}$. (B) Pt NPs were formed first, and Cu(acac) $)_{2}$ was added to the washed particles. Cu NPs were formed first and $\mathrm{Pt}(\mathrm{acac})_{2}$ was added to (C) washed Cu NPs. Inset: low-magnification showing also a Cu NP. (D) unwashed Cu NPs
