* v.s. - very strong, s. - strong, m. - medium, w. - weak.

Analysis of Intermolecular Interactions by means of molecular Voronoi-Dirichlet polyhedra. Intermolecular interactions in the structures of $\mathbf{2}$ and $\mathbf{3}$ were analyzed using the method of molecular Voronoi-Dirichlet (VD) polyhedra. This method allows one to describe all types of interatomic interactions automatically from one background and without a human factor. The VD polyhedron of an atom is a convex polyhedron of minimum volume, containing this point, and bounded by perpendicular planes, which pass through middle points of segments, connecting this point with all other points. Therefore VD polyhedron represents the shape of an atom in a structure of a compound. Each face of a VD polyhedron belongs to two atoms, A and B, and can be characterized by a rank (RF), which is the number of chemical bonds in the shortest chain connecting A and B . Thus, $R F=1$ for all covalent bonds, and $R F=2$ for $A$ and $B$ atoms in the chain $A-D-B$. If a face of the VD polyhedron of atom $A$ is generated with atom $B$ from another molecule (or chain, or layer), the rank of the A...B contact is set to zero, because there is no bonding chain connecting A and B. Molecular VD polyhedron results from the integration of VD polyhedra of atoms comprising a molecule. During this procedure all inner faces, corresponding to covalent interactions $(\mathrm{RF}=1)$ and intramolecular contacts ( $\mathrm{RF} \geq 2$ ), vanish inside a molecular VD polyhedron. Therefore, the faceting of a molecular VD polyhedron is formed only by faces with $\mathrm{RF}=0$, and each of them corresponds to a given contact between two atoms of neighboring molecules. Partial contributions $\Delta_{A / Z}$ of each type of contacts can be unambiguously estimated in percents by calculating the relative surface areas $S_{A / Z}$ of the corresponding faces of molecular VD polyhedron.

| Total | 602 | 1.90-5.01 | 922.4 | 100.0 |

* All possible types of intermolecular contacts $A / Z$ with the rank of VD polyhedra equal to zero are taken into account. $k$ - number of contacts, $d$ - range of interatomic $A \ldots Z$ distances, $S_{A / Z}$ - total area of faces of VD polyhedron, corresponding to contacts $A / Z$, and $\Delta_{A / Z}$ - partial contribution of $A / Z$ interactions into the total area of faces of molecular VD polyhedron, corresponding to one formula unit of the compound.
