COMPARISON BETWEEN THE FRENKLACH AND BITTNER-HOWARD MECHANISMS

We could make reference to the paper by Kislov, Mebel & alii,^[1] namely to their Figure 1 (p 913) and Table 1, from which ΔE_{ZPE} values are obtained to draw **Figure 1 below** [G3(MP2,CC) data]. There, the process A3-A3a-A4b-A5-N1 (green) corresponds to the Bittner-Howard variant,^[2] while the sequence A3-A10-A11-A12-A13-N1 (magenta) corresponds to the steps suggested by by Frenklach & coworkers.^[3] A branching occurs right from the beginning in the magenta curve, corresponding to simple H loss (upper curve) or to a +H/-H₂ process. A similar branching occurs in the green curve at the end. The first barrier is 4.5 kcal mol⁻¹ high for the Bittner-Howard curve, while it is 6.2 kcal mol⁻¹ for the Frenklach curve. Both curves converge to naphthalene (N1). The conclusion in ref. 1 is "The calculations allowed us, for the first time, to consider the HACA network as a whole, using the most reliable potential energy surfaces, which are expected to be accurate within 1-2 kcal/mol. the reactions involved in various HACA sequences are demonstrated to have relatively low barriers and high rate constants under combustion conditions. A comparison of the significance of different HACA mechanisms (e.g., Frenklach's, alternative Frenklach's, and Bittner and Howard's routes) in PAH growth can be made in the future...". Then, in another paper by Ahlrichs & coworkers^[4] is concluded that the two pathways are similarly viable ("As a summary, we find that the Bittner–Howard mechanism is slightly favored, ... This result is in line with that of Bauschlicher et al. [ref 5 here] for the analogous reaction of benzene and two acetylene to form naphthalene"). In conclusion, given that the purpose of this investigation is to assess if adsorption of the growing system R on a soot platelet P could affect (and how) the growth itself, we believe that any of the two variants discussed here was eligible.

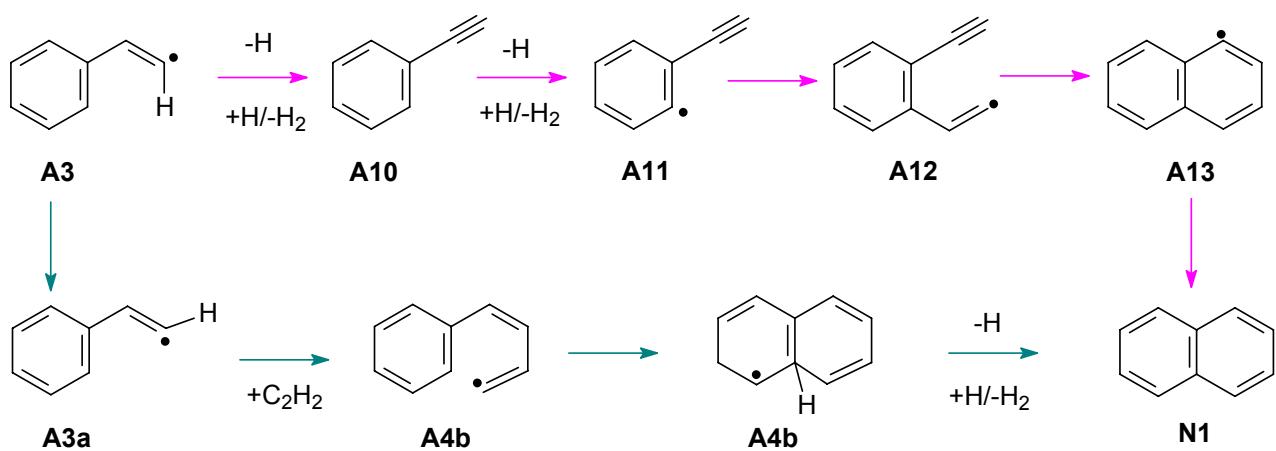

Figure 1

RESULTS ON THE “PERPENDICULAR” ARRANGEMENT

In the main text, emphasis is put on the results obtained for the || layout, because there is indication that this “graphite-like” arrangement is favoured as soon as the system’s size grows beyond some limit (with consequent higher probability of being adsorbed). Figure 1 in the paper, which has been obtained with a rather limited basis set, with the purpose of just seeing a trend [however, the data are corrected for the Basis Set Superposition Error (BSSE)].

For the \perp adsorption (**Table A**), the reference is again the || complex **3**, because the \perp complex **3** (4 kcal mol⁻¹ higher in terms of E, with BSSE correction) is kinetically very unstable.

- 1) The critical points and barriers for the channel **3-5-6** come out to be the very same already defined for the || arrangement, since the growing species slips sideways and abandons the \perp orientation.
- 2) The ring closure **3-4** requires overcoming barriers higher, to some extent, than those assessed for the gas-phase and || cases.
- 3) As regards chain lengthening from **3** to **8**, estimates based on hypotheses A and B would indicate again that chain extension is not competitive, in particular at higher temperatures.
- 4) If we consider that, for larger growing systems, the || adsorption mode has to be expected to be more stable, the data collected for the \perp case appear to be less important. For this reason, emphasis has been put, in the main text, on the results obtained for the || arrangement.

Table A. “Particle-phase” system in the \perp arrangement. Free energy differences.
