^a Number of hydrogen ligands on the metal cluster. ^b Relative stability of the hydrogenated cluster; see text, Eq. (1).

^c Number of unpaired electrons in the complex. ^d Ir_b – metal atoms at the base of the trigonal pyramid; Ir_t – iridium center at the apex of the cluster, see Figure S1 below.

^e Average nearest-neighbor distance of the metal moiety. ^f Difference between the largest and the smallest nearest-neighbor distances of the optimized structures.

^g Ir-H distances for H adsorption at a distorted bridge site are given as pairs of values, Ir_b-H/Ir_t-H. For terminal hydrogen atoms only average values are provided; subscripts t and b denote distances of H atoms coordinated on-top at Ir_t and Ir_b atoms, respectively. In the structures [Ir₄H_n]^{q+} with high hydrogen loading, for n = 6, 9 or 12, pairs of closely situated hydrogen atoms, i.e. activated H₂ molecules, are indicated their average Ir-H distance and their H-H distances (provided in parentheses, italics). These latter Ir-H distances are larger than average Ir-H distances for terminal bonding and are given as last entries, separately for each pair.

^h Ir-Ir distances exceeding 290 pm (Ir_b-Ir_t = 308 pm in [Ir₄H₉]³⁺; Ir_b-Ir_t = 291 pm in [Ir₄H₁₂]³⁺) are not included in the calculation of the average $\langle \text{Ir-Ir} \rangle$.

Table S2. Various characteristics calculated for the bare metal clusters $[Ir_4]^{q+}$ and their hydrogenated congeners $[Ir_4H_n]^{q+}$ ($q = 0-3$): HOMO-LUMO gap, in eV; ionization potential, IP in eV; Mulliken charge of the Ir_4 moiety, MC(Ir_4) in e; average energy, ε , and the corresponding range, δ , in eV, of Ir 2p, 4f, and 5s levels, and the average shift of all levels, $\langle\Delta\varepsilon\rangle$ in eV.

	gap	IP	MC(Ir_4)	Ir 2p		Ir 4f		Ir 5s		$\langle\Delta\varepsilon\rangle$

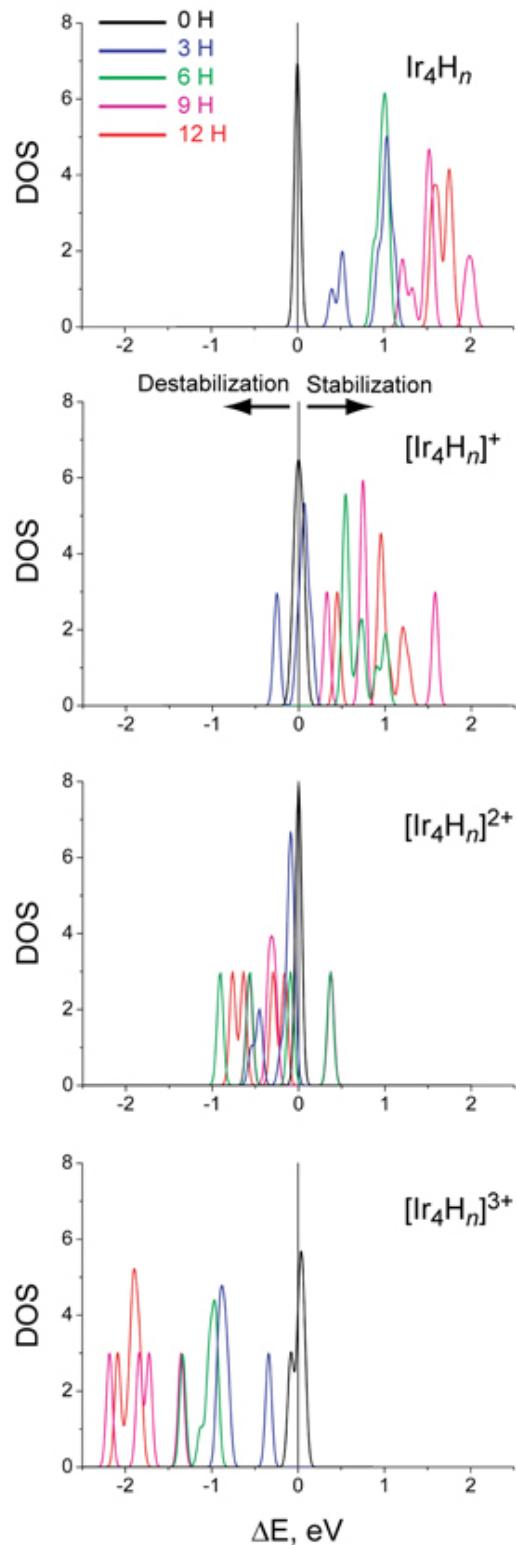

Figure S1. DOS plots for Ir 2p core levels of Ir centers of the bare clusters $[\text{Ir}_4]^{q+}$ and the hydrogenated clusters $[\text{Ir}_4\text{H}_n]^{q+}$ ($q = 0–3$), relative to the energy of the Ir 2p level of the Ir_4 cluster with corresponding charge q . The 2p levels of $[\text{Ir}_4]^{3+}$ form two groups of different energies; therefore an average value is used to estimate of the energy shifts of the hydrogenated species. The energies of the Ir 2p levels of the bare clusters are -11572.9 eV in Ir_4 , -11578.5 eV in $[\text{Ir}_4]^+$, -11584.5 eV in $[\text{Ir}_4]^{2+}$, and -11591.0 eV in $[\text{Ir}_4]^{3+}$.

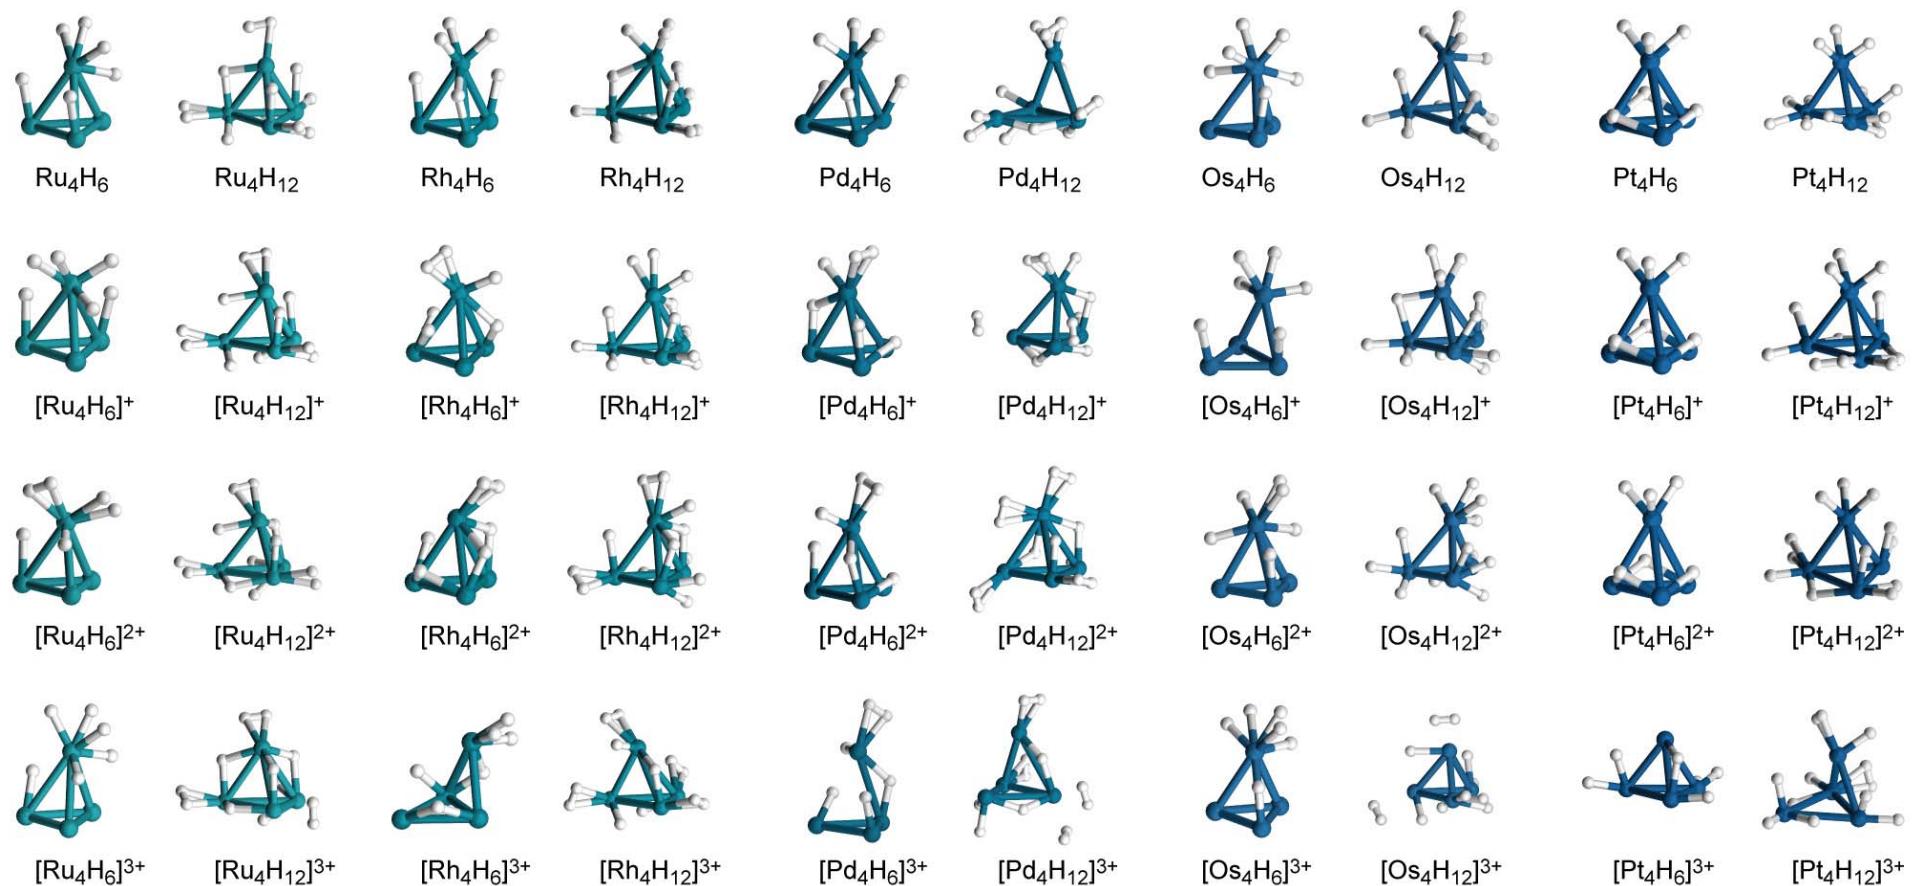

Figure S2. Optimized structures of $[M_4H_n]^{q+}$ species for $q = 0, 1, 2, 3$ and $n = 6, 12$.

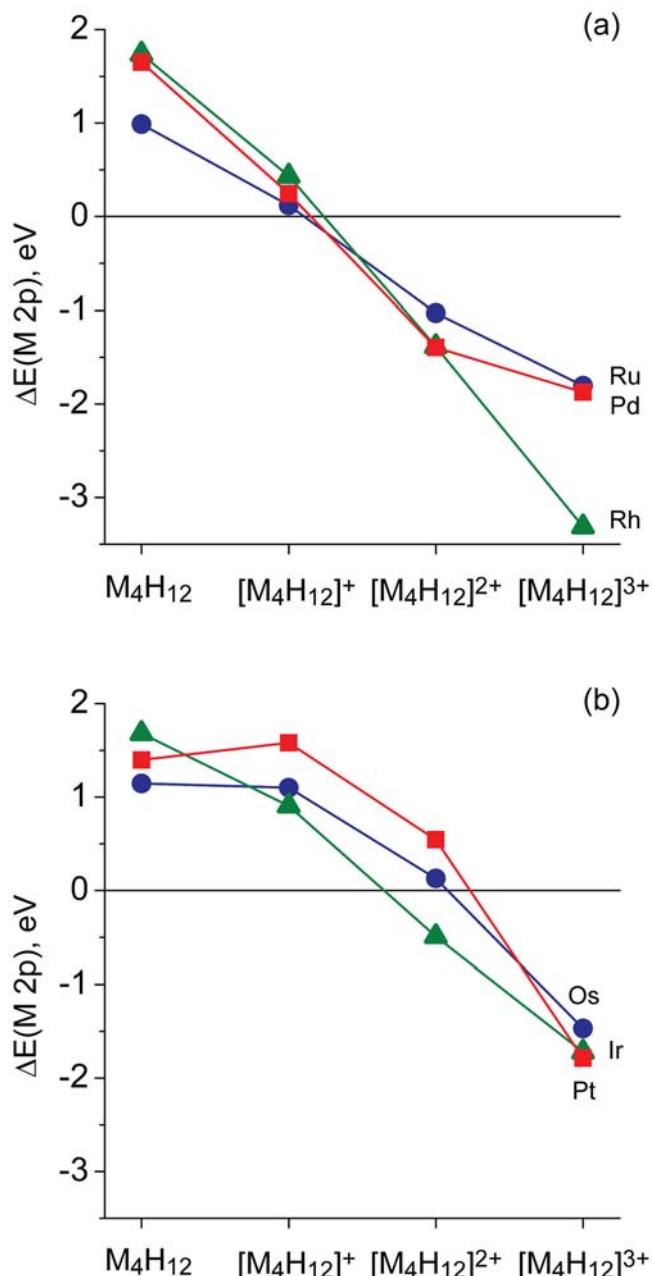

Figure S3. Variations of the average shifts of the M 2p levels in $[M_4H_{12}]^{q+}$ clusters with the total charge of the complexes of the (a) 4d and (b) 5d transition metals.
