Calculation of Specific Capacitances

The areal capacitance (mF/cm^2) of individual GF electrodes was calculated by using the following equation:

$$C = \frac{2 \times I \times t}{S \times V} \quad (1)$$

where S (cm^2) is surface area of the fiber electrode (cylindrical surface area: $S=2\pi rL$, r is radius of the fiber and L is the length of fiber); I (mA) is the discharging current; t (s) is the discharging time; V (V) is the potential voltage window.

The energy density (mWh/cm^2) and power density (mW/cm^2) of SC were calculated using the following equations:

$$E = \frac{C \times V^2}{2 \times 3600} \quad (2)$$

$$P = \frac{V \times I}{S} \quad (3)$$
