1. Examples for the planar B₁₈(-), B₂₀(-) and elongated B₁₆(0) cluster.

1.1 B₁₈(-):

The anionic B₁₈ cluster consists of an inner 6-atom triangulation, surrounded by an outer ring of thirteen atoms. The energy correlation diagrams (in Hartree), relative to the ground root are given in Tables 1 and 2 for σ and π orbitals respectively. As indicated in the Table 7, some σ -levels have a mixed label, due to strong orbital hybridization.

Table 1. Correlation of DFT σ -orbital energies and particle-on-a-disk spectrum.

In Figure 1 we plot the correlation diagram, again noting the bimodal aspects of the slopes, related to the basic orbital composition of the in-plane orbitals. Figure 2(original paper) shows the orbitals with maximum number of radial and angular nodes. There are at maximum two radial nodes (3σ), exactly as in the case of the B₁₃ cluster. The existence of an outer ring with twelve atoms gives rise to a wave with twelve sign changes, based on 2p-orbitals on the twelve outer

atoms, forming a ring with six angular nodes. The $m=6$ angular quantum number is represented by the Greek character ι (jota).

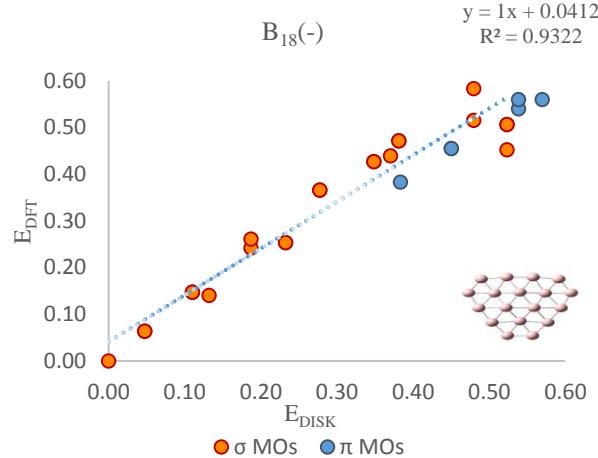

Figure 1. $B_{18}(-)$: correlation between DFT orbital energies and particle-on-a-disk spectrum

1.2 $B_{20}(-)$:

The anionic B_{20} cluster consists of a triple arrangement, with one central atom, surrounded by a hexagon, and an outer ring of 13 atoms. The energy correlations (in Hartree), relative to the ground root are given in Tables 3 and 4 for σ and π orbitals respectively.

Figure 3 shows the correlation plot with the characteristic change of slope. Figure 2(original paper) represents the 3σ -orbital with the two radial nodes. The orbital with the highest number of angular nodes is again a 1ι -orbital with twelve sign changes. How does this fit in with the 13 atoms on the outer ring? This is explained by group theory. A wave with m angular nodes will change $2m$ times when going around a ring. So for a ring with $2m$ atoms this maximal sign change can be achieved by a function which transforms as $\cos(m\varphi)$. As a result this function will transform irreducibly in the ideal point group C_{2m} and attain the highest ring quantum number allowed by that point group. For a ring with an odd number $2m+1$ of atoms, the irreducible representation with the highest ring quantum number in the point group would require a half-integral quantum number $m+1/2$, which is however a spinor representation instead of a real orbital representation. As a result the highest orbital quantum number in C_{2m+1} is also equal to m . Note however that this irrep will be twofold degenerate. This is confirmed by the observation of two 1ι orbitals in Table 3.

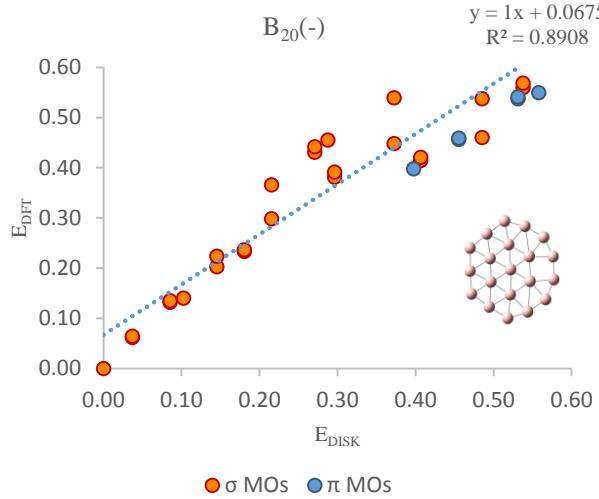

Figure 3. $B_{20}(-)$: correlation between DFT orbital energies and particle-on-a-disk spectrum

1.3 Elongated $B_{16}(0)$:

In Table 5 we list the orbital energies for $B_{16}(0)$ with the corresponding rectangular quantum numbers. In spite of the crude model applied, the rectangular box provides a very accurate description of the spectrum. Both the principal series ($n_x, 1$) and ($1, n_y$) are present, as well as several combination modes. The highest longitudinal quantum number is equal to 6, while the transversal quantum number cannot exceed 4. The HOMO-4 and HOMO-6 have pronounced densities on the capping atoms and cannot be assigned with the rectangular quantum numbers.
