1. To explore the conversion of quinoline during the heating time could be neglected?

1.0 mmol quinoline, 2.0 mL water and 35 mg catalyst were transferred to a Teflon-lined autoclave and the hydrogen was charged to the desired pressure after removing the air. After the autoclave was heated to 363 K in about 25 min without stirring. The autoclave was cooled to room temperature. All the products were taken out and the autoclave was washed with ethanol for 3 times (3.0 mL×3) to collect the products. The catalyst was separated by centrifugation. The liquid phase was analyzed by GC.

2. To explore is the leached Ru nanoparticles as the catalytic species?

The followed experiments was designed: Exp. (1). 1.0 mmol of quinoline, 2.0 mL of water and 3.0 MPa of hydrogen was introduced into the autoclave and reacted for 5 h at 363 K; Exp. (2). Ru-SiO₂@mSiO₂ (0.67 mol% Ru relative to quinoline), 2 mL water and 3.0 MPa of hydrogen was introduced into the autoclave and reacted for 5 h at 363 K, the catalyst was separated by filtration and the water was used as the solvent in the next experiment; Exp. (3). 1.0 mmol of quinoline, 2.0 mL water which was collected in Exp. (2) and 3.0 MPa of hydrogen was introduced into the autoclave and reacted for 5 h at 363 K. The results were listed in **Table S1**. Exp. (1) shows that we could exclude the metal particles absorbed on the liner tube in the autoclave as the catalytic species. Result in Exp. (3) shows that although there was trace amount

Ru leaching, the leached Ru was not as the catalytic species. (Note: the liner tube was bathed in chloronitrous acid at 303 K for 30 min, then bathed in concentrated nitric acid at 353 K for 3 h to remove all icons. The liner tube was washed by amount of water and dried at 353 K for 5 hours in vacuum before use.)

Entry	Reaction Components	Conversion (%)
Exp. (1)	quinoline, water and hydrogen	No reaction
Exp. (2)	catalyst, water and hydrogen	No reaction
Exp. (3)	quinoline, water ^a and hydrogen	No reaction

Table S1. Reaction performance in different reaction components

a. Collected from Exp. (2)

Reaction conditions: 5 h at 363 K

3 Synthesis of Ru/SiO₂·xH₂O catalyst

In typically, 500 mg of silica with the size distribution about 300-400 meshes was dispersed in the mixture of 25 mL ethanol and 0.1 mL NH₃·H₂O, then 10 mg Ru³⁺ was added and stirred for 24 h. After that, 5.0 mL of NaBH₄ solution was dropped into the suspension to reduce the Ru³⁺. The solid was filtered and dried at 308 K in vacuum. The catalyst was denominated as Ru/SiO₂·xH₂O. The Ru-loading (2%) was determined by ICP-AES

4. Synthesis of Ru/SiO₂-spheres catalyst

In typically, 0.70 mL NH₃·H₂O, 30 mL ethanol and 2.5 mL deionized water were stirred for 1 h at ambient temperature, then 1.9 mL TEOS was added and stirred for 6 h to get the silica core. Then 20 mg Ru³⁺ was added and the stirring continued for another 3 h. After that, 5.0 mL NaBH₄ solution was dropped into the suspension to reduce the Ru³⁺. The suspension was filtered and dried in vacuum. The product was denominated as Ru/SiO₂-Spheres. The Ru-loading (2%) was determined by ICP-AES.

5. Preparation of composite of quinoline adsorbed on the Ru-SiO₂@mSiO₂

100 mg catalyst and 2.0 mL quinoline were mixed together and stirred for 24 h at room temperature, the excess quinoline was distilled under vacuum at 393K. The solid was dried at 333K under vacuum for 24 h before detected by IR and Solid-state ^{13}C NMR.

6. Computational method

The method was as follows: Geometry optimizations were performed using the density functional theory (DFT) with the Beck's three-parameter nonlocal exchange functional and the gradient-corrected functional of Lee, Yang, and Parr (B3LYP) [1, 2, 3] and 6-31++G(d,p) basis set. The harmonic vibrational frequencies were also calculated at the same level to characterize the nature of the stationary point as true minimum with no imaginary. The NMR was calculated at the same level using GIAO method. All calculations were carried out using Gaussian 03 program [4]. The mainnetwork structures of the silica were proved as $\{(\text{HO})\text{Si}(\text{OSi})_3\}$ and $\{(\text{HO})_2\text{Si}(\text{OSi})_2\}$ by solid-state ^{29}Si NMR. The silica of the catalyst was built as $\text{HOSi}[\text{OSi}(\text{OH})_3]_3$ in the computational model.
