Supplementary Information Tuning Cellulose Pyrolysis Chemistry: Selective Decarbonylation via Catalyst-Impregnated Pyrolysis

Matthew S. Mettler, Alex D. Paulsen, Dionisios G. Vlachos, Paul J. Dauenhauer

Summary

This supplementary material section supports the data and conclusions presented in the main body of the paper. It contains a detailed breakdown of all oxygenate products detected in our catalyst impregnated pyrolysis experiments; additional results from catalyst-support impregnated pyrolysis (i.e., no metals); and catalyst metal and support surface areas.

Additional Results

Detailed furan yields are reported in the paper. Other pyrolysis-oil components detected in our experiments include levoglucosan, anhydroglucofuranose, glyceraldehyde and formic acid (see Table 1 and 2 for a comprehensive list). In the case of the Pd/C and Pd/SiO₂ experiments, levoglucosan (the most abundant product of cellulose pyrolysis) yield parallels that of the total pyrolysis oil yield.

The effect of various supports on condensed-phase cellulose pyrolysis chemistry is also reported in the supplementary section. Our results show that SiO_2 and C are the most inert support materials with the least effect on the pyrolysis product distribution (Figures 1 and 2). We show that for SiO_2 there is little effect on pyrolysis product yields for several biomass starting materials (see Table 3 for a comprehensive list).

For the catalysts tested in this work, metal surface areas (Table 4) were measured using H₂ chemisorption (except for Pd, Ni, and Co catalysts, where CO chemisorption was used) and found to consistent with previous work with these materials $(1.1 - 6.2 \text{ m}^2/\text{g})$. Additionally, N₂ physisorption (BET) measurements (Table 5) show that Al₂O₃ and SiO₂ have the higher support surface areas (220 and 89 m²/g) compared to carbon (15 m²/g). It is important to note that carbon catalysts have similar metal surface areas to SiO₂ catalysts, for the same metal weight loading which shows that carbon is better at dispersing the metals compared to SiO₂.

Additional Experimental Details

Catalyst impregnated pyrolysis experiments were conducted at 500 °C with millimeter-scale powder samples. Twenty Seven vapor products were detected in addition to char. CO and CO₂ were detected using a Thermal Conductivity Detector (TCD) while all other C1-C6 oxygenates were detected using both an FID and Mass Spectrometer. Oxygenate identities were based on FID retention times as well as mass spectra. Burn off was used to quantify char for all catalysts except those that were carbon-supported, since support oxidation would give artificially high char yields. Samples were pyrolyzed using a drop tube reactor (Frontier 2020 Pyrolyzer) with quartz wall and a furnace capable of reaching 800 °C. Previous work has shown that pyrolysis products such as levoglucosan do not breakdown in the quartz furnace despite the high temperature because of the ten millisecond residence time employed.

Carbon supported catalysts and Pd/Al_2O_3 were purchased from Sigma-Aldrich, Pt/SiO_2 was purchased from STREM Chemicals, and all other catalysts were prepared via incipient wetness impregnation. The weight loading for each of the catalysts is shown in the header of Tables 1 and 2. In general, metals were added at 1.7, 5 and 10 wt% to achieve the desired metal surface area (1.1 - 6.2 m²/g).

Table 3. Twenty seven products were identified and quantified for cellulose co-pyrolysis with eight different support materials.

Abbreviations: DAGP, dianhydroglucopyranose; ADGH, 1,5-anhydro-4-deoxy-D-glycero-hex-1-en-3-ulose; CPHM, 2-hydroxy-3-methyl-2-cyclopenten-1-one

| Catalyst | Surface Area [m ² /g] | Dispersion [%] |
|----------------|----------------------------------|----------------|
| 1.7 Pt/Alumina | 2.70 | 64 |
| 10Pd/Alumina | 6.24 | 14 |
| 5Pt/Carbon | 5.16 | 42 |
| 10Pd/Carbon | 6.19 | 14 |
| 5Pt/Silica | 1.27 | 10 |
| 10Ni/Alumina | 2.51 | 3.8 |
| 10Co/Alumina | 1.11 | 1.6 |
| 5Pd/Silica | 1.95 | 4.4 |

Table 4. Metal surface area for supported metal catalysts. Measurements were conducted using chemisoption with CO as the titration gas for Pd, Ni, and Co and H_2 for Pt.

Table 5. Eight support materials examined in impregnated pyrolysis of cellulose. BET surface area was measured using nitrogen adsorption. Particle size was measured using the Mastersizer 2000 and detailed plots of the particle size distribution for each support material are included in the supplementary section. R² values describe the variation between pyrolysis of cellulose with and without the support material and are also listed in Figure 1.

| Support | BET Surface Area [m ² /g] | Particle Size [µm] |
|------------------|---|-----------------------|
| Aluminum Oxide | 89 | 2.8 |
| Titanium Dioxide | 3.6 | 3.9 |
| Zirconium Oxide | 21 | 7.1 |
| Magnesium Oxide | 120 | 41 |
| Tungsten Carbide | 1.3 | 3.6 |
| Calcium Oxide | 7.9 | 60 |
| Carbon | 15 | 5.9 |
| Silicon Dioxide | 220 | 130 |

Figure 1. Parity plots comparing cellulose pyrolysis products with and without a catalyst support. All data points of an inert support fall on the parity line y = x. Included in each plot is the 'coefficient of determination' (R^2) value calculated using only yield values below 10%. A value of one represents a perfectly inert support.

Figure 2 Parity plots comparing four different saccharides pyrolyzed with and without silicon dioxide. Included in each plot is the 'coefficient of determination' (R²) value where a value of one represents a perfectly inert support.
