## Experimental section

## General remarks

NMR spectra were recorded on a JEOL ECZ 400 S spectrometer at 400 MHz for ${ }^{1} \mathrm{H} \mathrm{NMR}$ and 100 MHz for ${ }^{13} \mathrm{C}$ NMR, with residual protic solvent as the internal reference. Chemical shifts are given in ppm $(\delta)$ and coupling constants (J) are given in Hertz (Hz). Mass spectrometry data were obtained from the EPSRC National Mass Spectrometry Facility at Swansea University. UV-vis spectroscopy was carried out on a Varian Cary 50 Bio UV-vis spectrophotometer. All commercially available starting material used in synthesis were obtained from Sigma Aldrich, Fluorochem, and Alfa Aesar and were used without further purification. Deionised water was obtained from a Millipore Milli-Q reagent water system. All solvents were obtained from Fisher Scientific, VWR, and Honeywell. Solvents were dried according to the procedure by William et al. ${ }^{1}$

HPLC analysis were performed on Agilent HPLC system. The separations were performed on a Gemini ${ }^{\oplus}$ $5 \mu \mathrm{~m}$ C18 110 Å LC column $150 \times 4.6 \mathrm{~mm}$ (Phenomenex, UK) at a flow rate of $1 \mathrm{~mL} \mathrm{~min}^{-1}$, with a mobile phase consisting of $0.1 \%$ TFA in water (solvent A) and $0.1 \%$ TFA in acetonitrile (solvent B). Gradient [time/min](solvent A:solvent B): [0-2](85:15). [2-17](85:15-40:60). [17-18](40:60-5:95). [18-23](5:95). [23-24](5:95-85:15). [24-26](85:15)

## Synthesis of $\left[\operatorname{Re}(\mathrm{CO})_{3} \mathrm{Br}_{3}\right]\left[\mathrm{NEt}_{4}\right]_{2}{ }^{4}$

$\mathrm{NEt}_{4} \mathrm{Br}$ tetraethyl ammonium bromide ( $230 \mathrm{mg}, 1.09 \mathrm{mmol}$ ) was slurried in 2,5,8-trioxanonane (diglyme) ( 40 mL ) under dry nitrogen and heated to $80^{\circ} \mathrm{C}$. A suspension of $\left[\operatorname{ReBr}(\mathrm{CO})_{5}\right](200 \mathrm{mg}, 0.49$ mmol ) in warm $50^{\circ} \mathrm{C}$ diglyme ( 2.7 mL ) was slowly added. The mixture was left at $115{ }^{\circ} \mathrm{C}$ for 5 hours during which time a white precipitate formed. The reaction mixture was filtered whilst hot and washed with several portions of cold diglyme, diethyl ether and dried under suction filtration. The resulting white powder was then slurried in ethanol $\left(3 \mathrm{~cm}^{3}\right)$ to remove unreacted $\mathrm{NEt}_{4} \mathrm{Br}$. Filtration and drying in vacuo yielded the product as a white powder ( $315 \mathrm{mg}, 0.410 \mathrm{mmol}, 84 \%$ ).

## Radiolabelling with ${ }^{99 m}$ Tc

## Synthesis of $\left[{ }^{99 m} \mathrm{Tc}(\mathrm{CO})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]^{+}$

$\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{CO})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]^{+}$was prepared as described previously. ${ }^{5}$ Briefly, sodium tetraborate decahydrate ( $2.9 \mathrm{mg}, 7.6 \mu \mathrm{~mol}$ ), sodium carbonate ( $7.8 \mathrm{mg}, 73.6 \mu \mathrm{~mol}$ ), potassium sodium tartrate tetrahydrate $(9.0 \mathrm{mg}, 31.9 \mu \mathrm{~mol})$ and disodium boranocarbonate ( $4.5 \mathrm{mg}, 43.3 \mu \mathrm{~mol}$ ) was purged with argon for 10 minutes, after which $\mathrm{Na}\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}\right] \mathrm{TcO}_{4}$ in saline ( $1 \mathrm{~mL}, 407-658 \mathrm{MBq}$ ) was added and heated at $99{ }^{\circ} \mathrm{C}$ for 20 minutes. $\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{CO})_{3}\right]^{+}$was analysed using radio-HPLC and radio-TLC. Radio-TLC was carried out on Kieselgel $60 \mathrm{~F}_{254}$ plates ( $1 \times 10 \mathrm{~cm}$, Merck) with mobile phase of $1 \% \mathrm{HCl}$ in methanol ( $\mathrm{R}_{\mathrm{f}}=0.2-0.8$ ). For reactions at $\mathrm{pH} 7.4,\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{CO})_{3}\right]^{+}$was neutralised with $1 \mathrm{M} \mathrm{HCl}(160 \mu \mathrm{~L})$ and was buffered with PBS $1 \times$ ( $\mathrm{pH} 7.4,100 \mu \mathrm{~L}$ ). pH was measured using universal indicator paper.

## ${ }^{99 m}$ Tc radiolabelling

Porphyrin-conjugate ( $500 \mu \mathrm{~L}, 0.1 \mathrm{mM}$ and $500 \mu \mathrm{~L}, 1 \mathrm{mM}$ ) in saline was degassed for 10 minutes using argon. Previously prepared $\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{CO})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]^{+}(40-45 \mathrm{MBq}, 500 \mu \mathrm{~L})$ was added to the degassed ligand solution and heated at $90^{\circ} \mathrm{C}$ for 30 minutes. After cooling, radio-HPLC and radio-TLC analysis were carried out to determine radiochemical yield. Radio-TLC was carried out on Kieselgel $60 \mathrm{~F}_{254}$ plates ( $1 \times 10 \mathrm{~cm}$, Merck) with mobile phase of 0.1 M aqueous $1: 1$ trisodium citrate:citric acid. This mobile phase gives clear separation between labelled-complex ( $\mathrm{R}_{\mathrm{f}}=0$ ) and unreduced ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}$ ] and unreacted $\left[{ }^{99 \mathrm{mTc}}(\mathrm{CO})_{3}\right]^{+}$(both with $\mathrm{R}_{\mathrm{f}}=1$ ).

## Determination of partition coefficient ( $\log D_{7.4}$ )

Lipophilicity was determined using the shake-flask method. Briefly, a solution of tracer (ca. 0.1 MBq ) in PBS was diluted to $500 \mu \mathrm{~L}$ in PBS and $500 \mu \mathrm{~L}$ of octanol was added. The solution was vortex mixed at room temperature for 15 minutes. The solutions were centrifuged, a portion of each layer was read in a gamma counter (Wallac). The results are presented as a Log of the ratio of counts in the water:octanol layers and as an average and standard deviation of experiments in triplicate.

## FACS protocol

PSMA expression was determined by flow cytometry. 70-80\% confluent cells were harvested, aliquoted at $3 \times 10^{5}$ cells per sample and centrifuged for 5 min at $200 \times \mathrm{g}$. The supernatant was removed and the cell pellet was resuspended in $97 \mu \mathrm{~L}$ of FACS buffer ( 1 X PBS, $5 \mathrm{mM} \mathrm{MgCl}{ }_{2}, 1 \mathrm{mM}$ $\mathrm{CaCl}_{2}$ ) supplemented with $2 \% \mathrm{FBS}$. Following the addition of $3 \mu \mathrm{~L}$ of the relevant antibody (for a final volume of $100 \mu \mathrm{~L}$ ), cells were incubated for 1 h at room temperature and in the dark. Cells were incubated with either phycoerythrin (PE)-conjugated anti-PSMA monoclonal antibody (GCP-05, Abcam) or PE-conjugated mouse IgG1 (R\&D Systems) isotype control antibody to account for nonspecific binding. After the incubation, unbound antibody was removed with three washes ( $200 \mu \mathrm{~L}$ ) with FACS buffer. After the last wash, the cell pellet was resuspended in $400 \mu \mathrm{~L}$ of FACS buffer supplemented with $1 \%$ formaldehyde and transferred into FACS tubes. Acquisition was carried out on a BD FACSCaliburTM flow cytometer. For each sample, a gate was manually drawn around the population of interest and 10000 events were acquired. The data was analysed with BD CellQuestTM Pro.

## In vitro toxicity and phototoxicity evaluation

A stock solution of $\mathbf{2 ,}[\operatorname{Re}(2)], 4$, and $[\operatorname{Re}(4)]$ were made by dissolving in medium (1-2 mL ). The stock was sterilized by filtration through $0.22 \mu \mathrm{~m}$ PES syringe filter unit (Millex-GP). The concentration of the stock was calculated by UV-vis spectroscopy using the extinction coefficient of the conjugate. The stock was diluted further with medium to give the desired concentration range. Phototoxicity and toxicity of 2 and [ $\operatorname{Re}(2)]$ were evaluated on human colorectal adenocarcinoma (HT-29) cells, by incubation of varying concentration of nanoparticles for 1 hour. Phototoxicity and toxicity of 4 and [Re(4)] were evaluated on native and transfected prostate carcinoma cells, DU145 and DU145-PSMA, by incubation of varying concentration for 30 mins. $800 \mu \mathrm{l}$ of the appropriate cells, adjusted to a concentration of $1 \times 10^{6}$ cells $/ \mathrm{ml}$ in medium with L-glutamine, was added to $200 \mu \mathrm{~L}$ conjugate solution in a $12 \times 75 \mathrm{~mm}$ polystyrene FACS tube (Falcon). The cells were allowed to incubate in the dark for 1 hour at $37{ }^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$, after which they were centrifuged with $3 \times$ excess of medium to remove unbound compounds. The pellet of cells was resuspended in 1 ml medium and $4 \times 100 \mu \mathrm{l}$ of each concentration was put in two 96 wells plates. One plate was irradiated with white light to a dose of 20 $\mathrm{J} \mathrm{cm}^{-2}$ while the other serves as a dark control. After irradiation, $5 \mu \mathrm{l}$ of foetal bovine serum (FBS) was added to each well and the plates are returned to the incubator overnight. After 18 to 24 hours, the cell viability was determined using 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT) colorimetric assay. $10 \mu \mathrm{~L}$ of 12 mM MTT solution was added to each well and incubated between 1 and 4 hours at $37^{\circ} \mathrm{C}$ to allow MTT metabolisation. The crystals formed were dissolved by adding $150 \mu \mathrm{~L}$ of acid-alcohol mixture ( 0.04 M HCl in absolute 2-propanol). The absorbance at 570 nm was measured on a Biotek ELX800 Universal Microplate Reader. The results were expressed with respect to control values.
