#### **Experimental sections**

## Chemicals

All chemical reagents were purchased from *J&K* Chemical and *Aladdin*. All the chemical reagents were of analytical grade and used without any further purification.

### **Preparation of Samples**

The synthesis of CN (g-C<sub>3</sub>N<sub>4</sub>) and RCN-*x* (reduced g-C<sub>3</sub>N<sub>4</sub>) was based on the investigation reported by Yanrong Zhang. <sup>[1]</sup> Typically, 10 g melamine was placed into a crucible with a lid and then heated up to 450 °C for 4 h at a rate of 5 °C/min in a muffle furnace. The obtained product was grounded with an agate mortar and then washed with hot deionized water (80 °C) three times, also dried in vacuum at 70 °C for 12 h. The obtained whitish powder was denoted as CN. The RCN-*x* were thoroughly blended CN with different amount of NaBH<sub>4</sub> (x = 3, 5, 7, represents the weight ratio of CN:NaBH<sub>4</sub> were 1:3, 1:5, 1:7) in a mortar, and then thermally treated at 370 °C in argon atmosphere for 30 min with a heating rate of 5 °C/min. The product was washed with hot deionized water (80 °C) three times. Then it was dried in vacuum at 70 °C for 12 h. The obtained yellow powder was denoted as RCN-*x*.

#### **Characterizations**

The phase and crystal structure of the samples were performed on a powder X-ray diffraction (XRD, D/MAX 2500, Rigaku Co., Japan) with Cu K $\alpha$  radiation ( $\lambda = 0.154$  nm). The morphology study was performed on a field emission scanning electron microscopy (FE-SEM, S4800, Hitachi, Japan) and a transmission electron microscopy (TEM, JEM-F200, JEOL, Japan). Fourier transform infrared spectroscopy (FT-IR) were recorded on a spectrometer (Nicolet-6700, Thermo Scientific, USA). N/C atomic ratio of CN and RCN was determined by an Elemental analyzer (Vario Micro cube, Elementar,

Germany). The electron spin resonance (ESR) spectra measurements were executed on JES-FA200 Xband spectrometer. The surface chemical analysis was investigated by X-ray photoelectron spectroscopy (XPS, ESCALAB-250Xi, Thermo Scientific, USA). The absorption spectra of the samples were converted from the UV-vis diffuse reflectance spectra measured on UV-vis spectrophotometer (UV-2700, Shimadzu, Japan). The photoluminescence (PL) spectrum measurements and fluorescence lifetimes were detected by a spectrofluorometer (Fluorolog-3, Horiba Jobin Yvon, USA) with and excitation wavelength of 375 nm.

#### Photocatalytic Activity Evaluation

Photocatalytic methane conversion experiments were carried out in a stainless-steel autoclave (Figure S1) containing a Teflon liner vessel (working volume, 50 mL) equipped with a quartz window to allow light irradiation. Typically, 20 mg catalyst was dispersed in 20 mL deionized water followed by ultrasonication for 5 min. The Teflon vessel was placed in the well of the autoclave, and the autoclave was sealed. Then, the sealed autoclave was pressurized with 0.1 MPa O<sub>2</sub> (purity, 99.999%) and 2 MPa CH<sub>4</sub> (purity, 99.999%) following purging O<sub>2</sub> five times. Subsequently, the autoclave was loaded into a water circulation system keeping the reaction temperature at 25±1 °C, and the solution was stirring at 200 rpm. 300 W Xe lamp (Figure S2, light intensity, 100 mW cm<sup>-2</sup>) was employed as the light source. Other experiments operated at different reaction conditions will be mentioned extra. The obtained liquid products were quantified by <sup>1</sup>H nuclear magnetic resonance (NMR, Avance III, Bruker, Germany, 400 MHz). Typically, 0.5 mL liquid product was mixed with 0.1 mL of D2O, and 0.02 µl dimethyl sulfoxide (DMSO, Heowns, 99.9%) was added into as an internal standard. The gas phase product was gleaned by a gas sampling bag and quantified by gas chromatography (GC, Shimadzu 2010) with a flame ionization detector (FID).

The concentration of  $H_2O_2$  was quantified with a colorimetric DPD method. <sup>[2]</sup> The concentration of  $H_2O_2$  was monitored by the absorption of the solution at 551nm which was recorded using the UV-vis spectrometer.

#### Electrochemical measurements

The electrochemical measurements were carried out on an electrochemical workstation (CHI 760 E, Shanghai, China) with a three-electrode cell in an aqueous solution containing 0.1 M Na<sub>2</sub>SO<sub>4</sub>. The CN and RCN electrodes which were used as working electrodes were prepared by drop-coating on the FTO glass. The Ag/AgCl (3 M KCl) electrode and a Pt wire were employed as the reference electrode and counter electrode, respectively. All the potentials were referenced to the Ag/AgCl electrode without specification. The 300 W Xe lamp was used as the light source.

The ethanol selectivity was calculated through the following equation:

 $Selectivity = \frac{Productivity of ethanol}{Productivity of EtOH + Productivity of MeOH + Productivity of HCOOH + Productivity of CO_2}$ (S1)

Figure S7. The GC spectrum of CO<sub>2</sub> produced over CN in photocatalytic conversion of methane.

Figure S8. <sup>1</sup>H NMR of methane oxidation product over RCN-5.

DMSO was adopted as an internal standard in NMR test.

Figure S9. Photocatalytic methane conversion over different amount of RCN-5.

Figure S10. Control experimental results of the photocatalytic reaction over RCN-5.

The control experiments were carried out to illustrate the crucial role of oxygen and light. Without oxygen or light, no obvious ethanol production could be observed. The results revealed that both oxygen and light played a significant role in efficient photocatalytic methane conversion.
