## 1 Diagonal Hamiltonian Matrix Elements

In the EOP-TI/CIS model, the $E_{1}$ and $E_{2}$ matrix elements are approximated by neglecting the influence of environment, quantified by $\Delta E_{e \rightarrow g}^{X}(Y)$, because we found it to be a relatively small contribution, even at very close inter-chromophore distances. The $E_{3}$ and $E_{4}$ matrix elements require evaluation of the Coulombic interaction between HOMO and LUMO orbitals of isolated monomers. In the EOP-TI/CIS model, this contribution is represented by the cumulative atomic multipole moments (CAMM) expansion of the HOMO and LUMO electron densities, including all the terms having up to $R^{-5}$ distance dependence. In Table S1 all these diagonal matrix elements are shown for ethylene and 7AC dimers at selected geometries.

Table S1 Comparison of the diagonal Hamiltonian matrix elements for the studied $\mathrm{TI} / \mathrm{CIS}$ models. The results (given in eV ) were obtained for the ethylene and 7AC dimers at three selected geometries at the CIS/6-31G(d) level. Due to symmetry of the studied model systems, $E_{1}=E_{2}$ and $E_{3}=E_{4}$. References to equations in the main text, that were used to compute the matrix elements, are also given.

## 2 Timings for Computations of $\mathrm{TI} / \mathrm{CIS}$ EET Couplings

Table S3 Comparison of the CPU times of $V^{\mathrm{TI}}$ coupling computation for the studied $\mathrm{TI} / \mathrm{CIS}$ models. The results (given in s) were obtained for the ethylene and 7AC dimers at their equilibrium geometries at the CIS/6-31G(d) level. The reported timings, calculated as an average of 10 runs (except PS-I), do not include the time to solve SCF or CIS problems for the monomers but in the case of $V^{\mathrm{TI}}(\mathscr{F})$ the time to solve the SCF problem for the whole complex is obviously included. All calculations were performed on a single core of 1.2 GHz AMD EPYC ${ }^{\text {TM }} 7301$ 16-Core processor with the same SCF and CIS convergence settings and thresholds. Only in the case of PS-I calculations we used the more efficient 3.1 GHz Intel Xeon ${ }^{\text {TM }}$ E5-2687W CPU.

|  | (Ethylene) 2 | $(7 \mathrm{AC})_{2}$ | PS-I |
| :--- | ---: | :---: | ---: |
| $V^{\mathrm{TI}}(\mathscr{F})$ | 9.20 | $3.70 \cdot 10^{3}$ | - |
| $V^{\mathrm{TI}}\left(\mathscr{F}_{0}^{\mathrm{DFI}}\right)$ | 3.22 | $1.55 \cdot 10^{3}$ | - |
| $V^{\mathrm{TI}}\left(\mathscr{F}_{0}\right)$ | 3.18 | $1.53 \cdot 10^{3}$ | $4.92 \cdot 10^{5}$ |
| $V^{\mathrm{TI}}\left(\mathscr{F}_{0}^{\mathrm{EOP}}\right)$ | $5.82 \cdot 10^{-3}$ | $7.89 \cdot 10^{-2}$ | 5.69 |
| $V_{\text {Coul }}^{\mathrm{TrCAMM}}$ | $2.80 \cdot 10^{-5}$ | $6.74 \cdot 10^{-5}$ | $3.10 \cdot 10^{-2}$ |

## 3 Basis Set Extension Effects

All the results in the main article were obtained assuming $6-31 \mathrm{G}(\mathrm{d})$ basis set and in the case of EOP-TI/CIS calculations aug-cc-pVDZ-JKFIT auxiliary EOP basis set. In Figure S1 the values of TI/CIS EET couplings and their selected components, calculated assuming cc-pVXZ basis sets for $\mathrm{X}=\mathrm{D}, \mathrm{T}, \mathrm{Q}$, are plotted with respect to growing basis set cardinal number.

All the EOP-TI/CIS results were obtained assuming the corresponding aug-cc-pVXZ-JKFIT auxiliary EOP basis set. However, the differences between results obtained using aug-cc-pVDZ-JKFIT auxiliary basis and the one corresponding to a given orbital basis were negligible. In particular we noticed that using larger JKFIT basis than the one dedicated to a given orbital basis resulted in differences below $1 \mathrm{~cm}^{-1}$. In case of calculations assuming smaller JKFIT basis (for instance aug-cc-pVDZ-JKFIT instead of aug-cc-pVTZ-JKFIT) led to differences not exceeding a few reciprocal centimeters. Thus we would recommend using aug-cc-pVDZ-JKFIT set as EOP auxiliary basis if available.

The choice of orbital basis is more important, however, also does not seem to be critical considering the overall accuracy of the TI/CIS approach. Analysis of the trends obtained for various components shows that the $V_{\text {Direct }}^{\mathrm{TI}}$ is almost independent of basis set choice due to opposite trends for the Coulomb and exchange contributions. The indirect components are much more sensitive to the basis set choice. For instance the cc-pVDZ value of $V_{\text {Indirect }}^{\mathrm{TI}}$ is roughly $55 \%$ of that obtained in the cc-pVTZ and $40 \%$ of that for cc-pVQZ, however, it seems to saturate rather quickly with the basis set extension. Note also that for the studied model systems the indirect contribution at equilibrium geometries constitutes only roughly $20-30 \%$ of the total TI/CIS coupling. Finally, it is interesting to note that the TI/CIS values converge quickly to the exact ESD coupling with basis set extension.

Fig. S1 TI/CIS EET couplings and their components calculated at various level of approximation (indicated by labels in the center of a given panel) for symmetric stacked ethylene dimer at its equlibrium geometry as a function of cc-pVXZ orbital basis set cardinal number. In the case of EOP-TI calculation the corresponding aug-cc-pVXZ-JKFIT basis set was used.

## Basis set extension effects

## 4 Partitioning of EET couplings in the special pair of PS-I

Table S4 Partitioning of EET couplings computed between the lowestlying bright ${ }^{1} \pi \pi^{*}$ states of two chlorophylls of the special pair of PS-I at various levels of approximation to $\mathrm{TI} / \mathrm{CIS}$ method. Indentation indicates constituents of a given term or it's approximation. All the results, given in $\mathrm{cm}^{-1}$, were computed assuming $6-31 \mathrm{G}(\mathrm{d})$ basis set. The superscript ' $M$ ' indicates values estimated using the Mulliken approximation: Eq. (53) for the EOP-TI model, and Eq. (51) for remaining models (see main text). The $V^{\mathrm{TI}(3)}$ values in the EOP-TI results were computed assuming either the distributed multipolar expansion truncated on $|R|^{-5}$ terms or on atomic monopoles (values in parentheses) in $V_{\mathrm{CT}}$ calculations.

| TI/CIS model | $\mathrm{TI}\left(\mathscr{F}_{0}\right)$ | EOP |

Cartesian coordinates (in A) of stacked 7-aminocoumarin (7AC) dimer. The structure was obtained by superposition of two flat 7AC molecules at their equilibrium geometries located at MP2 $/ 6-31 \mathrm{~g}(\mathrm{~d})$ level and shifted with respect to intermolecular axis. Such a rigid potential energy scan shows minimum at $R_{\mathrm{AB}}=3.6 \AA$. The corresponding structure is reported below.
