I. Details on training neural networks

In the embedded atom neural network (EANN) approach¹ and its piecewise version (PEANN), the weights and biases of atomic NNs along with the atomic expansion coefficients were determined by minimizing the cost function defined by root-mean-errors between ab initio potential energies and atomic forces with respect to Cartesian coordinates and corresponding NN outputs²,

$$S(\mathbf{w}) = \sum_{i=1}^{N_{data}} \left[(E_i^{NN} - E_i^{Ref})^2 + \eta \left| \vec{\mathbf{F}}_i^{NN} - \vec{\mathbf{F}}_i^{Ref} \right|^2 \right] / N_{data}.$$
 (S1)

Here, **w** is a collection of all adjustable parameters, N_{data} is the number of configurations in the training set. E_i^{NN} , E_i^{Ref} , $\vec{\mathbf{F}}_i^{NN}$ and $\vec{\mathbf{F}}_i^{Ref}$ are potential energies and atomic force vectors of *i*th configuration obtained by NN and reference ab initio calculations, respectively. Note that each E_i^{NN} and $\vec{\mathbf{F}}_i^{NN}$ are the sum of atomic NN outputs and for the atomic NN parameters are identical for same element. An efficient hybrid extreme machine learning Levenberg-Marquardt (ELM-LM) algorithm was employed to optimize these adjustable parameters³.

For all systems discussed in this work, the NN structures consist of two hidden layers. To make a fair comparison, the number of neurons in each hidden layer, the number of descriptors, as well as the cutoff radius (r_c) were all kept the same for in EANN and PEANN potentials of each system. Table S1 gives such information for the four benchmark condensed phase systems, namely Cu, Ge, Mo, and water. Also compared in Table S1 are the computational costs of evaluating individually the internuclear distances within r_c , the density-like structural descriptors, and NNs (plus the rest minor contributions), respectively. Other hyperparameters to determine the densitylike descriptors are listed in Tables S1-S5 for PEANN and Tables S6-S9 for EANN, for Cu, Ge, Mo, and water in sequence. Note that for the water system, we have applied the CUR matrix decomposition algorithm⁴ to select the optimal descriptors that best represent the training set, as used by Ceriotti and coworkers to optimize the selection of Behler-Parrinello type atom centered symmetry functions⁵.

II. Molecular dynamics simulations

To demonstrate the comparable performance of EANN and PEANN as other machine learning models, as done in Ref. 12, we have predicted material properties such as phonon dispersion curves, as well as energies and forces at unseen structures, taking Mo as an example (this is already the system with largest errors). To this end, in Fig. S1, we compare the DFT calculated phonon spectrum for $3 \times 3 \times 3$ bulk Mo with the results predicted by all machine learning models discussed in the main text. In addition, following Zuo et al.¹², we have performed 250 ps NVT classical molecular dynamics (MD) simulations for a $3 \times 3 \times 3$ bulk Mo with a 0.1 fs time step at 1300K maintained with Andersen thermostat, and extracted 40 snapshots with a time interval of 2.5 ps. It should be noted that none of the training and testing data were obtained from such high temperature MD simulations and the sampled configurations could be therefore very different and unknown, serving as good candidates for testing the extrapolability of machine learning potentials. The energy and force error distributions of our EANN and PEANN model are compared in Fig S2 with other machine learning models whose results are extracted from Ref. 12.

To validate the accuracy of our PEANN and EANN potentials for liquid water, we compare the O-O, O-H and H-H radial distribution functions (RDFs) of liquid water obtained by the classical molecular dynamics (MD) simulations using the TIP4P model in Ref. ⁶, Behler-Parrinello NN (BPNN) potential in Ref. 7, EANN and PEANN potentials in this work, respectively. MD simulations have been performed with 64 water molecules in a cubic box with its side length of 12.42 Å at temperature of 300 K. A total of 20 ps NVT MD simulations with a time step of 0.2 fs. The Andersen thermostat⁸ was used for keeping the temperature in the simulations of the PEANN/EANN potentials in a modified VENUS code⁹, while the Nose-Hoover Chains algorithm¹⁰ was used for the TIP4P and BPNN models implemented with LAMMPS¹¹, respectively. It is found that the TIP4P force field requires a longer cutoff radius and long-range corrections to yield the correct description of RDFs as shown in Fig. 4, and our setup thus follows the original publication⁶ where the short-range interactions were truncated at 7.75 Å.
