### Supporting information

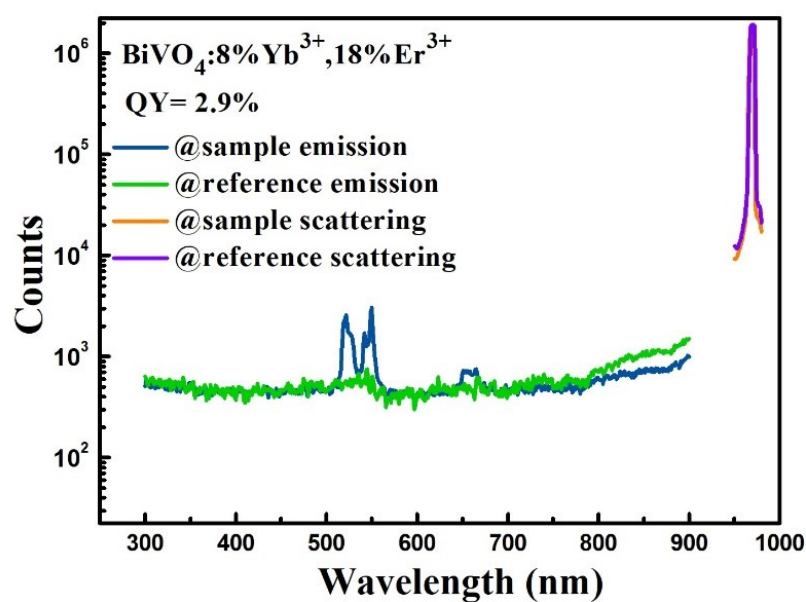

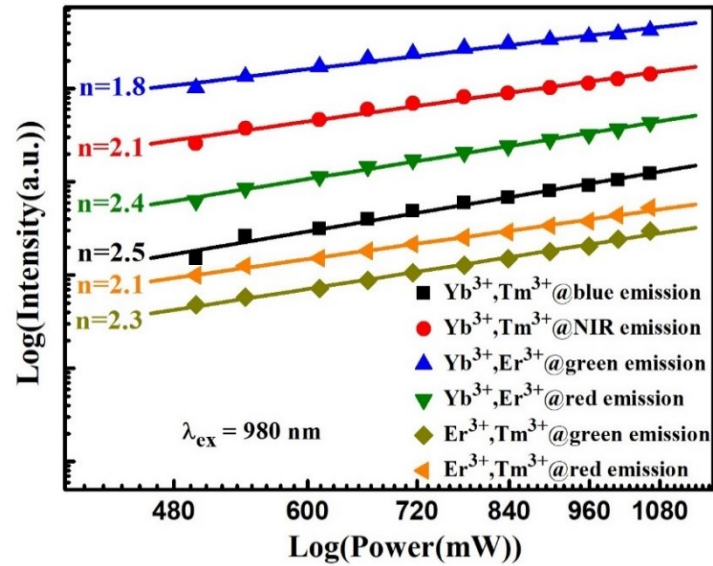

Figure S1. Absolute quantum yield (QY) measurements of the BiVO<sub>4</sub>:8%Yb<sup>3+</sup>, 18%Er<sup>3+</sup> sample at excitation of 980 nm laser (power density: 38 W/cm<sup>2</sup>) by using the fluorescence spectrometer (Edinburgh FS5) equipped with an integrating sphere. The standard BaSO<sub>4</sub> was used as the reference sample. Blue line: sample emission ( $E_{sam}$ ), green line: reference sample emission ( $E_{ref}$ ), yellow line: sample excitation scattering ( $L_{sam}$ ), violet line: reference sample excitation

scattering ( $L_{ref}$ ). The QY was calculated based on the equation of  $QY = [E_{sam} - E_{ref}] / [L_{ref} - L_{sam}]$

[1] [2].

**Figure S2.** Logarithmic curves of luminescence integrated intensity (I) of  $\text{BiVO}_4$  doped with  $\text{Yb}^{3+}/\text{Tm}^{3+}$ ,  $\text{Yb}^{3+}/\text{Er}^{3+}$  and  $\text{Er}^{3+}/\text{Tm}^{3+}$  samples as a function of excitation power (P) under 980 nm pumping.

**Figure S3.** The UCL emission spectra of (a)  $\text{BiVO}_4:a\%\text{Er}^{3+},1\%\text{Tm}^{3+}$  ( $a = 5, 8, 10, 15, 30, 40, 50$ ) and (b)  $\text{BiVO}_4:b\%\text{Yb}^{3+},0.3\%\text{Tm}^{3+}$  ( $b = 40, 50, 60, 70, 80, 90, 99$ ) (The inset is the enlarged view of

blue emission) at 980 nm excitation.

As shown in Figure S3a, the UCL intensity of the  $\text{Er}^{3+}/\text{Tm}^{3+}$  ions doped  $\text{BiVO}_4$  sample increases gradually to a maximum value as the increasing of  $\text{Er}^{3+}$  doping concentration with  $\text{Tm}^{3+}$  concentration fixed at 1%, and then decreases after  $\text{Er}^{3+}$  doping content more than 30% at excitation of 980 nm. Similarly, the blue emission of  $\text{Yb}^{3+}/\text{Tm}^{3+}$  co-doped sample increases first and then decreases when increasing  $\text{Yb}^{3+}$  concentration at a fixed  $\text{Tm}^{3+}$  concentration of 1%, and the optimized doping concentrations of  $\text{Yb}^{3+}$  is found to be 70% as shown in Figure S3b.

**Figure S4.** Dependence of FIR values on 980 nm and 1550 nm laser irradiation times for  $\text{BiVO}_4:30\%\text{Er}^{3+},0.8\%\text{Tm}^{3+}$  samples.

The dependence of the FIR values of the two green emissions for  $\text{BiVO}_4:30\%\text{Er}^{3+},0.8\%\text{Tm}^{3+}$  sample on the laser irradiation times is shown in Figure S4. The low excitation power densities of  $19 \text{ mW}/\text{mm}^2$  and  $23 \text{ mW}/\text{mm}^2$  for 980 nm and 1550 nm lasers, respectively, were chosen to obtain

UCL spectra. The FIR curves of the two samples are relatively flat within the irradiation time of one hour, meaning that the effect of irradiation power densities used in this work on the FIR measurements can be neglected.
