S1.1 Estimation of the excited state lifetime needed to achieve a two-fold reduction in the lifetime of a photosensitiser by oxygen.

Using the Stern-Volmer equation $\tau_0/\tau = 1 + k\tau_0[\text{O}_2]$, (where τ_0 and τ are excited state lifetimes of PS* without and with the presence of oxygen, respectively), a 0.25 mM oxygen concentration in water under ambient temperature and pressure, and the upper limit of diffusion-controlled reaction k being $1.8 \times 10^{10} \text{ M}^{-1}\text{s}^{-1}$ in water,⁶ one estimates that a 220 ns excited state lifetime without the presence of oxygen would be required to achieve a two-fold reduction in the lifetime of PS* by oxygen, in the reaction potentially leading to ROS.

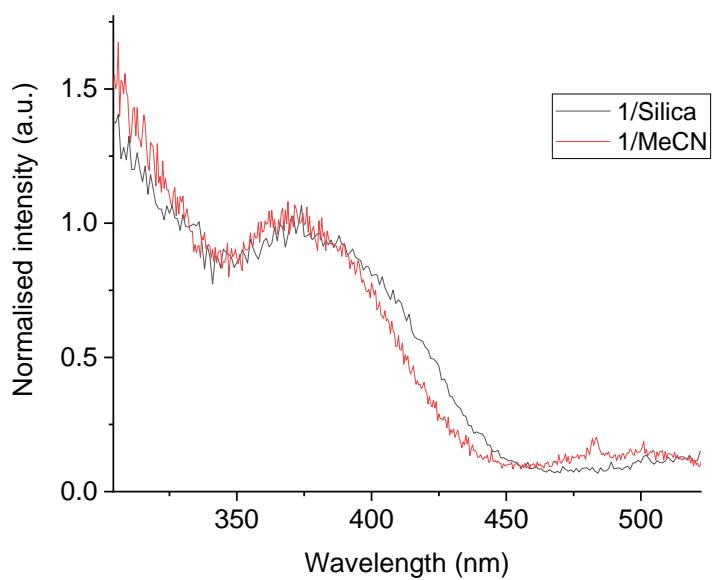

Figure S1. Normalized (to the signal at 373nm) excitation spectra of complex **1** in MeCN solution, and on silica (**1**-silica). Emission detection wavelength was 570 nm.

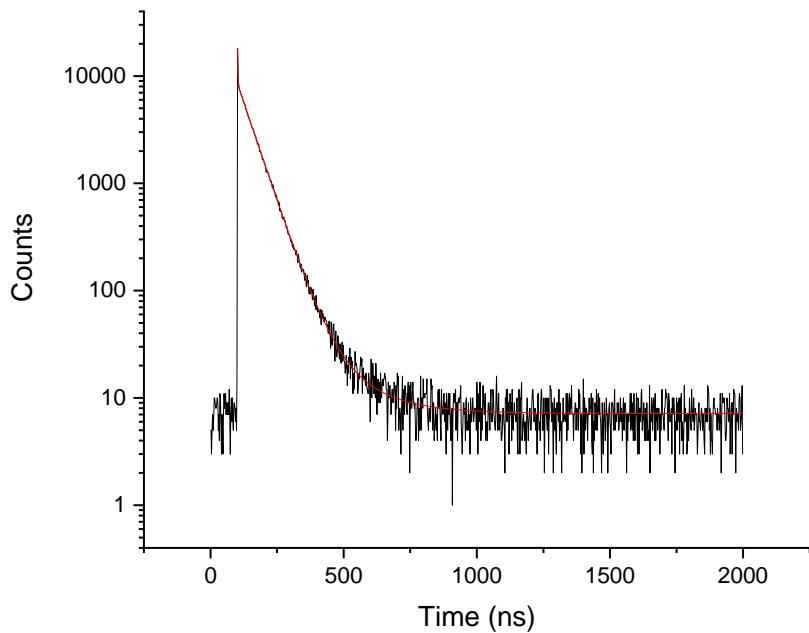

Figure S2. An emission decay trace of complex **1** in aerated MeCN solution (black line), excitation 405 nm (90 ps), registration in the range 525 – 575 nm. A principal decay component is 58 ns. A small contribution at early times is due to the instrument response function.

S3 Crystallographic data for complex **1**

The results of X-ray crystallographic study of a single crystal of **1** are given in Figure S8.

Intensity data was collected at 100 K on a Bruker D8 Venture diffractometer equipped with a Photon 100 CMOS detector using a CuK α microfocus X-ray source from a crystal mounted in fomblin oil on a MiTiGen microloop and cooled in a stream of cold N₂. Data were corrected for absorption using empirical methods (SADABS⁷) based upon symmetry equivalent reflections combined with measurements at different azimuthal angles⁸. The crystal structures were solved and refined against F2 values using ShelXT⁹ for solution and ShelXL¹⁰ for refinement accessed via the Olex2 program¹¹. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions with idealized geometries and then refined by employing a riding model and isotropic displacement parameters.

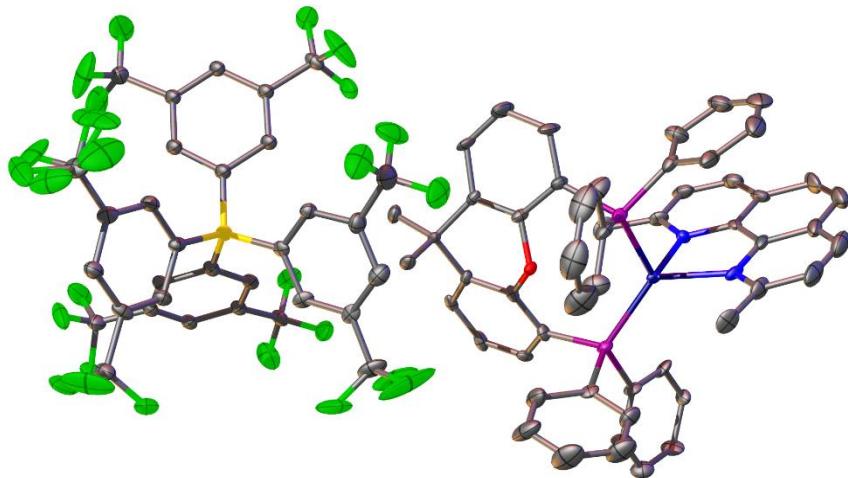

Figure S8. Structure of complex **1** obtained by single crystal X-ray crystallography. Thermal ellipsoids are drawn at 50% probability levels. Hydrogen atoms are omitted for clarity. C (grey), F (green), B (yellow), N (blue), O (red), P (purple). The structure is fully consistent with that published previously, and is given here to estimate the size of the $[\text{Cu}(\text{xanphos})(\text{dmp})]^+$ ion. See Table S2 for details.

S3.1 Calculating the volume of the pores in Silica gel used compared to the crystal structure.

The pore size is listed as 60 Å of the silica gel. Assuming this to be the diameter of the pore, and the pore to be hemispheres, the volume estimated using $\frac{2}{3}\pi r^3$ and $r = 30 \text{ \AA}$ would be $\sim 5.7 \times 10^4 \text{ \AA}^3$. The unit cell of the crystal is $3.9 \times 10^3 \text{ \AA}$ (see Table S2) suggesting that multiple unit cells could fit within a pore of the silica. Therefore, it can be assumed that some of the loaded complex could be within the pores on the silica.

The final R_1 was 0.1417 ($I > 2\sigma(I)$) and wR_2 was 0.2793 (all data).

S4 Determination of singlet oxygen yield using singlet oxygen probe

*Figure S9. Monitoring change in the emission spectrum of Singlet Oxygen Sensor Green in the presence of **1**-silica when irradiated with 10 mW cm^{-2} 405 nm light at varying time intervals. The intensity at 525 nm as a function of time is plotted in Figure 2 in the main text.*

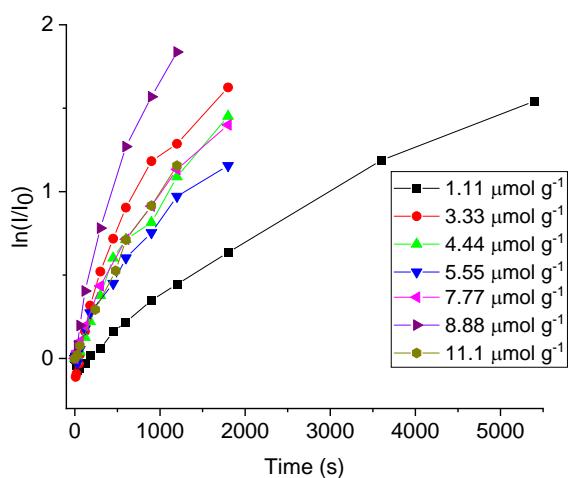

Figure S10. Monitoring change of a. emission intensity (I) at the emission maximum of Singlet Oxygen Sensor Green (525 nm), and b. $\ln(I/I_0)$ at SOSG emission maximum (525nm) as a function of time for different loading concentrations ($\mu\text{mol g}^{-1}$) of **1**-silica.

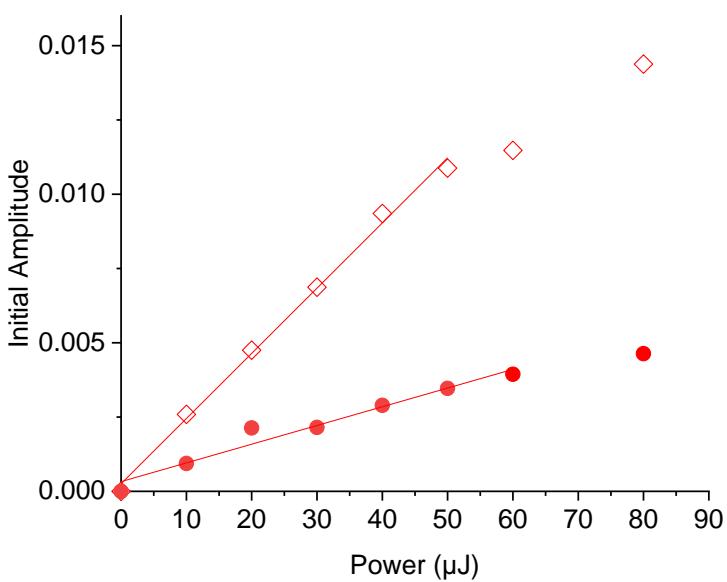

Figure S11. Direct measurement of singlet oxygen production in MeCN of complex **1** and perinapthenone (PN). The amplitude of singlet oxygen emission was measured at 1275 nm and extrapolated to zero time. The emission was measured as a function of laser excitation energy at 355 nm with an 8 ns pulse.

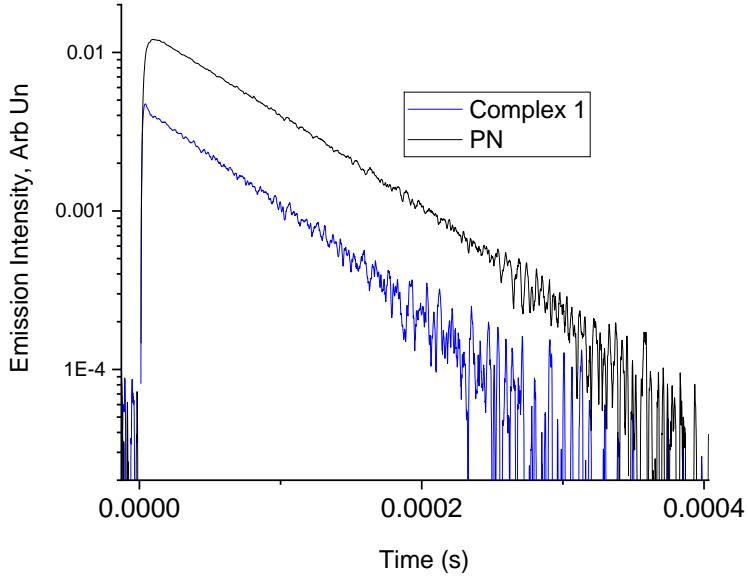

Figure S12. Decay trace of singlet oxygen emission at 1275nm (obtained by using a 355nm laser with 8ns pulse and a power of 80 μ J) in MeCN in the presence of Complex **1** and perinapthenone (PN). The figure illustrates that the lifetime of singlet oxygen is the same in both cases (72 μ s), therefore, no interaction between $^1\text{O}_2$ and complex **1** in its ground state is observed.

S5 Bacterial inactivation assay of MRSA in the presence of complex 1 in suspension

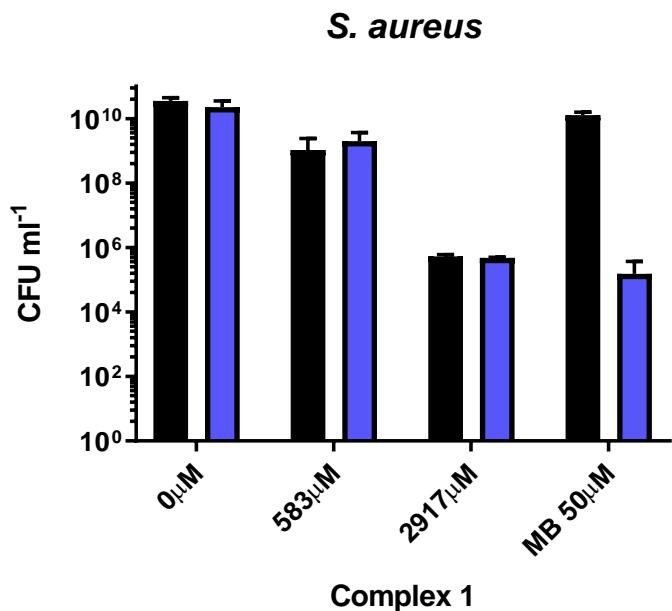

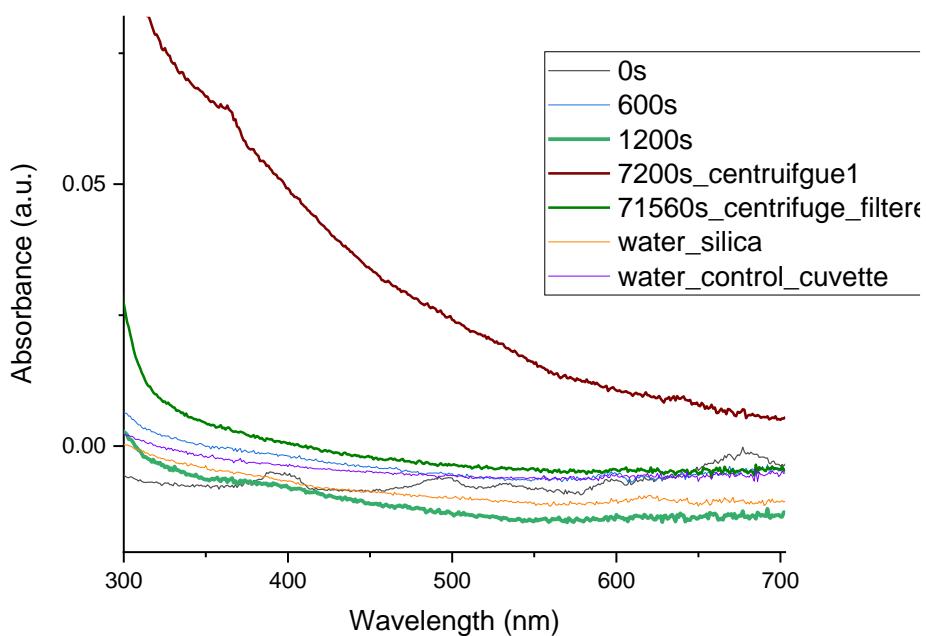

Figure S13. Bacterial viability assay measuring the colony forming units of *S. aureus* on its own ($0 \mu\text{M}$), in the presence of 1 mg ml^{-1} ($583 \mu\text{M}$) and 5 mg ml^{-1} ($2917 \mu\text{M}$) of complex 1, and methylene blue (MB) ($50 \mu\text{M}$). The samples were irradiated for 2 hours with 405 nm light at 17.5 mW cm^{-2} , total dose 126 J cm^{-2} (blue bars) or left in the dark for 2 hours (black bars).

S6 Stability of 1-silica

S6.1 Measuring the amount of leaching of complex 1 from silica through UV-Vis absorption of the suspension in water.

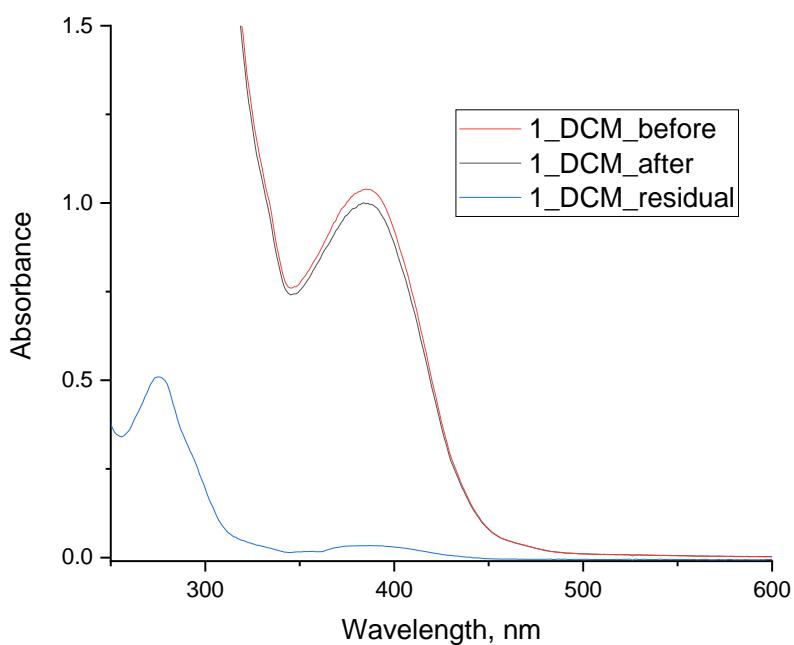

1-silica suspension (5 mg ml^{-1}) in water was stirred in a cuvette for 0s, 300s, 600s, 1200s, 1800s, 3600s and 7200s, figure S14. After being stirred a UV-Vis spectra of the solution was taken after letting the suspension settle in the cuvette. A final measurement was taken after 21 hours (71560s). In addition to settling the 7200s and 21 hour measurement were taken after using a centrifuge as the scatter from the silica remaining in suspension was too high. The supernatant of the 21 hour sample was also filtered due to high amounts of scatter. The lack of absorption spectra of **1** in the measurements taken suggests negligible solubility of the complex in solution. (The UV-Vis spectra are not normalised)

*Figure S14. UV-vis absorption spectra of **1**-silica suspension in water over time.*

S6.2 Measuring the amount of complex **1** before and after immobilisation on silica.

Uv-vis spectra of a solution of complex **1** in DCM (5 mg in 10ml) were recorded (Figure S15, **1_DCM_before**) before the complex (5mg) was dried onto silica (250 mg), equivalent to 10mg of complex **1** on 500mg of Silica as used in the antibacterial assays. After **1**-silica was removed, residual complex **1** remaining in the vessel was dissolved in 10ml of DCM and UV-vis measurement was taken (Figure S15, **1_DCM_residual**). **1**-Silica was the suspended in water and stirred for 2 hours. After 2 hours the solution was centrifuged and water was removed. 90mg of **1**-silica was recovered and complex **1** was removed using 3.6 ml of DCM (Figure S15, **1_DCM_after**). The difference in the before and after spectra is approximately equal to that of the residual measurement taken. This suggest that <0.3% of complex **1** was lost (by for example leaching) during the 2-hour experiment.

*Figure S15. UV-vis absorption spectra of complex **1** in DCM. Red line, solution (a): absorption spectrum of **1** prior to addition of silica (250 mg of silica in 10 ml of DCM, 5mg of complex **1**). Blue line, solution (b): The spectrum of the solution obtained by centrifuging silica, and filtering Black line (solution c): **1**-silica collected by centrifugation from solution “a” with silica added, stirred in water for 2 hrs, centrifuged, dried, and re-dissolved in DCM (90 mg of **1**-silica in 3.6 ml DCM, to match the originally taken 250 mg silica in 10 ml DCM).*
