## **Characterization results**

All peptides were synthesized via solid-phase peptide synthesis methods (SPPS) as described in the main content. 4-azidobutanoic acid was introduced to the N-terminus of the CLP via amidation reaction. An alkyne group from propargyl glycine was attached to the C-terminus of the ELP domain via SPPS. The facile conjugation of ELP and CLP via CuAAC "click" reaction was conducted as described in the main content (Fig. 1). The molecular weight of CLP, ELPs & ELP-CLP conjugates was verified via electrospray ionization mass spectrometry (ESI-MS) (Figure S1-S13). After purification with reverse-phase HPLC, conjugates with purity greater than 95% were obtained (Figure S14 & S15). The two peaks that are apparent in the chromatograms below are a result of CLP triple helix formation which combines a fraction of the ELP-CLP monomer into trimers, while a fraction of the conjugates remain as monomers. This mixture of ELP-CLP trimers and monomers under the HPLC experimental conditions results in the two peaks in the HPLC chromatogram. Our ESI-MS data indicate that there are few to no impurities in any of the peptides synthesized.

## **Coarse-grained simulation details**

In our coarse-grained model, the "H-bond" bead attraction strengths were chosen as the minimum interaction attraction strengths required to observe a shift in the transition point for  $F_4Y_2$ -(POG)<sub>8</sub> vs.  $F_6$ -(POG)<sub>8</sub>. Therefore, the CG model captures the phenomenon of tyrosine substitutions effects on the LCST while also using a minimalistic approach. The relative H-bond bead attraction strengths involving Y and all other residues (X = V, P, F or G) were varied in order to obtain the minimum relative interaction strengths. Fig. S17 shows results for cases where A) all Y residues had H-bond bead attraction strengths that were 1.5 times the H-bond bead attraction strength of all other residues, and C) H-bond bead attraction strengths that were 2.5 times the H-bond bead attraction strength of all other residues. A shift in the transition point was only observed for case C. Therefore, the optimized H-bond (i.e., LJ) parameters,  $\epsilon^{HB}$ , were set at 50.4 $\epsilon$  for Y-Y pairs, 31.9 $\epsilon$  for Y-X pairs, and 20.2 $\epsilon$  for X-X pairs where X can be any amino acid besides tyrosine, Y.

**Figure S16:** Ensemble average number of pairwise contacts per ELP coarse-grained (CG) bead vs. the strength of attractive pairwise interactions among ELP beads for (A) low H-bond bead attraction strengths ( $\varepsilon_{Y-Y} = 1.5 \varepsilon_{X-X}$ ), B) medium H-bond bead attraction strengths ( $\varepsilon_{Y-Y} = 1.75 \varepsilon_{X-X}$ ), and high H-bond bead attraction strengths ( $\varepsilon_{Y-Y} = 2.5 \varepsilon_{X-X}$ ).

**Figure S17** CD spectra showing a representative: Left: full-wavelength scan; Right: thermal unfolding profile at 225 nm for (GPO)<sub>8</sub>GG.

**Figure S18** Average hydrodynamic diameter as a function of temperature obtained from dynamic light scattering (DLS) characterization for the represented ELP-CLPs. The error bars represent the standard deviation of three different measurements from a representative synthetic batch.

Table S1 diameter and temperature conjugates					Hydrodynamic the corresponding
	ELP	CLP	Diameter (nm)	Temperature	for all the
	$F_6$	(GPO)8GG	~150 nm	31 °C	-
	$F_5Y$		~120 nm		
	$F_4Y_2$		~135 nm		
	$Y_2F_4$		~145 nm		
	$F_3Y_3$		~160 nm		
	$Y_3F_3$		~175 nm		
	F <sub>5</sub>	(GPO) <sub>8</sub> GG	~390 nm	40 °C	
	$F_4Y$		~400 nm		
	$F_3Y_2$		~390 nm		
	$Y_2F_3$		~390 nm		
	$F_2Y_3$		~425 nm		
	$Y_3F_2$		~430 nm		

Atomistic simulation details

**Figure S19:** Schematic showing A) parallel stacking interactions between nearby aromatic rings and B) T- or Y-shaped (i.e. perpendicular) stacking interactions between nearby aromatic rings.

**Figure S20:** Hydration analysis of tethered  $F_4Y_2$  showing the number of peptide-water hydrogen bonds ( $\langle N_{HB} \rangle$ ) plotted versus the number of water molecules in the 1<sup>st</sup> hydration shell of the peptide chain ( $\langle N_W \rangle$ ). Multiple hydration states are observed without an observable single LCST-like transition involving two distinct hydration states.

**Figure S21:** Simulation snapshots of tethered  $F_4Y_2$  in the A) the initial  $\beta$ -spiral configuration and in the B) final configuration after 200 ns; this confirms that the initial configuration is not retained in the simulation. Plots of number of turn structures ( $\beta$ ,  $\alpha$ , and  $\pi$ ) for C) tethered  $F_6$ ,  $F_5Y$ ,  $F_4Y_2$ , and D) tethered  $F_5$ ,  $F_4Y$ ,  $F_3Y_2$  at the end of each simulation run (200 ns).

**Figure S22:** Hydrogen bonding analyses for tethered  $F_4Y_2$ , and  $Y_2F_4$  (shown red, blue, and green, respectively) obtained from atomistic simulations: A) total peptide-peptide hydrogen bonds, B) inter-peptide hydrogen bonds, C) intra-peptide hydrogen bonds, D) peptide-water hydrogen bonds, and E)  $\beta$ ,  $\alpha$ , and  $\pi$  turns.

**Figure S23:** Effect of the tethering point/terminus on the  $\pi$ - $\pi$  stacking of ELP 6-mers (F<sub>6</sub> series) at high temperatures: (A,D) 65 °C, (B,E) 85 °C, and (C,F) 97 °C.

**Figure S24**: Effect of Y inclusion on the  $\pi$ - $\pi$  stacking of ELP 5-mers at low temperatures: (A,D,G) 5 °C, (B,E,H) 25 °C, and (C,F,I) 45 °C.
