1. Calculation of theoretical specific capacitance of pseudocapacitive nano-size V₂O₅

For pseudocapacitive nano-size V₂O₅ (extrinsic pseudocapacitive materials) [1], under ideal conditions (the extent of fractional coverage of surface or inner structure is 100%), its theoretical capacitance is calculated based on the following equation [1]:

$$C = \frac{nF}{mE} \quad (1)$$

where n is the mean number of the electrons transferred in the redox reaction, F is the Faraday constant, m is the molar mass of the metal oxide and E is the operating voltage window. Therefore, when V⁵⁺ is reduced to V⁴⁺ and $E = 1$ V, the theoretical capacitance is calculated as: $(2 \times 96485.3383 / 1.0 / 182) \text{ F g}^{-1} \approx 1060 \text{ F g}^{-1}$.

2. Pore characteristic parameters of NCN, V₂O₅ SMBs and NCN@V₂O₅ SMBs
