Section 1. Experimental Detail

EXPERIMENTAL SECTION

Materials. Ni(NO$_3$)$_2$·6H$_2$O (99%), Fe(NO$_3$)$_3$·9H$_2$O (99%), RhCl$_3$·3H$_2$O and NaOH (>98%) were all of analytical grade and obtained from Energy Chemical and were used directly without any further purification. N$_2$H$_4$·H$_2$O (80%) was purchased from Beijing Chemical Reagents Company.

Synthesis of NiFe. The NiFe was synthesized using a coprecipitation method according to the reference. A 20.0 ml solution composed 0.66 mmol Ni(NO$_3$)$_2$·6H$_2$O and 0.33 mmol Fe(NO$_3$)$_3$·9H$_2$O was added drop by drop to a three-necked flask with 20 ml deionized water by a peristaltic pump under magnetic stirring at 80 °C. In the meantime, a solution with 0.25 M NaOH was added to the system to maintain the pH of 10. The brown precipitates were collected by centrifugation and washed with deionized water for 3 times.

Synthesis of Bulk-NiFe. A aqueous solution composed of Ni(NO$_3$)$_2$·6H$_2$O (0.10 mol, 29.1 g) and Fe(NO$_3$)$_3$·9H$_2$O (0.05 mol, 20.20 g) in 70.0 mL deionized water was added drop by drop to an aqueous solution of NaOH (0.3 mol, 12.0 g) and Na$_2$CO$_3$ (0.95 mol, 10.0 g) in 100 mL deionized water with good stirring at 30 °C. After 20 min, at the end of the addition, the flask contents were heated at 65 °C for 18 h.

Synthesis of Rh/NiFe-x (x = 0, 0.5, 1.2, 2.7, 5.4). A 20.0 ml solution composed 0.66 mmol Ni(NO$_3$)$_2$·6H$_2$O, 0.33 mmol Fe(NO$_3$)$_3$·9H$_2$O and different amount of RhCl$_3$·3H$_2$O was added drop by drop to a three-necked flask with 20 ml deionized water
by a peristaltic pump under magnetic stirring at 80 °C. In the meantime, a solution with 0.25 M NaOH was added to the system to maintain the pH of 10. The brown precipitates were collected by centrifugation and washed with deionized water for 3 times. The x means the loading of Rh and corresponding to the RhCl₃·3H₂O amount of 0.0033 mmol, 0.0165 mmol, 0.033 mmol, 0.066 mmol, respectively.

**Computational details:**

**The structural model of LDH used to calculate the DOS and band structure:**

An ideal NiFe was built with the space group of R3-m, which contains 18 Ni atoms and 9 Fe atoms. The initial lattice parameters of 2-dimensinal layer are \( a = b = 3 \) Å. The supercell of NiFe was \( 3 \times 3 \times 1 \) in the \( a-, b- \) and \( c-\) directions with lattice parameters \( a = b = 9 \) Å, \( c = 25.65 \) Å, \( \alpha = \beta = 90^\circ, \gamma = 120^\circ \). Nitrate anion not carbonate anion was chosen as equilibrium charge anion in the interlayer space to simplify the calculation. The Rh/NiFe was built by replacing a Fe atom in the first layer by Rh atoms.

**The structural model of LDH used to calculate the substitution site of Rh atoms:**

An ideal NiFe was built with the space group of \( p\bar{3}m1 \), which contains 48 Ni atoms and 24 Fe atoms. The parameters of 2-dimensinal layer are the same as above. The supercell LDH was \( 12 \times 9 \times 1 \) in the \( a-, b- \) and \( c-\) directions with parameters \( a = 36 \) Å, \( b = 18 \) Å, \( c = 8.5 \) Å, \( \alpha = \beta = 90^\circ, \gamma = 120^\circ \). Then a Ni atom and a Fe atom were removed at appropriate position to form a NiFe-Matel vacancy (NiFe-Mv). Rh atom was filled in the Ni vacancy and Fe vacancy respectively to form a Rh/NiFe-Niv and Rh/NiFe-Fev.
Computational method:

The first principles density functional theory plus Hubbard U (DFT + U) calculation in this work were performed using the CASTEP module in Material Studio software package\(^1\). The values of $U - J (U_{\text{eff}})$ were 3.80 eV for Ni\(^{2+}\), 4.30 for Fe\(^{3+}\), respectively\(^2\)\(^-\)\(^4\). The Perdew-Burke-Ernzerhof (PBE) functional in generalized gradient approximation (GGA) was used to describe the exchange and correlation\(^5\) and the ultrasoft pseudopotential were applied to describe the ionic cores to improve transferability and reduce the number of plane waves required in the expansion of the Kohn-Sham orbitals. The potential energy surface was searched with Broyden-letcher-Goldfarb-Shanno (BFGS) algorithm\(^6\). The cutoff energy was set as 381.0 eV to balance the cost and effectiveness\(^7\). The geometry optimization was based on the following points: (1) an energy tolerance of $5.0 \times 10^{-5}$ eV/atom, (2) a maximum displacement tolerance of $5.0 \times 10^{-3}$ Å, and (3) a maximum force tolerance of 0.1 eV/Å.

XANES spectra were calculated by ab initio simulations using the FDMNES package. Comparing the result calculated using finite-difference method (FDM) and multiple scattering theory (MST) with experimental data, we implemented FDM in the FDMNES code since the full potential method is more suitable to deal with distorted structures. Then a 6 Å cluster radius was calculated to save CPU resources and time. To take into account the core-hole lifetime and other multielectronic phenomena occurring in the absorption process, a convolution procedure was applied to all calculated spectra presented in this work.
Section 2. Supporting Figures and Tables

**Figure S1.** Schematic illustration of $M^{3+}$ ions dispersed by $M^{2+}$ in LDHs with the ratio of $M^{2+}/M^{3+} = 2$ and surface OH groups.
By involving Ru and Pd into the LDHs using the same synthetic method, we found they have showed very different location, in which the Ru atoms are precisely located above the trivalent Fe site of the NiFe LDHs layer in the single atoms format (Chem. Sci., 2019, 10, 378-384.), while the Pd was demonstrated to be located on the layer of CoAl LDH in the form of nanoparticles (J. Energy Chem., 2020, 46, 1-7).
