Experimental Procedures

Chemicals

Hydrogen peroxide (H$_2$O$_2$, 30%), nitric acid (HNO$_3$, 65.0%~68.0%), sodium hydroxide (NaOH, 96.0%), salicylic acid (C$_7$H$_6$O$_3$, 99.5%), ammonium chloride (NH$_4$Cl, 99.5%), sodium citrate dehydrate (C$_6$H$_5$Na$_3$O$_7$·2H$_2$O, 99.0%) were purchased from Sinopharm Chemical Reagent Co., China. Hydrochloric acid (HCl, 35.0%~38.0%) and ethanol (C$_2$H$_5$OH, 99.7%) were obtained from Beijing Chemical Works, China. Hydrazine monohydrate (N$_2$H$_4$·H$_2$O, 99.0%), iron phthalocyanine (C$_{32}$H$_{16}$FeN$_8$, 96.0%) and dimethyl sulfoxide-d$_6$ (DMSO-d$_6$, deuterium for 99.9%) were obtained from Alfa Aesar, USA. Sodium nitroferricyanide dehydrate (C$_5$FeN$_6$Na$_2$O·2H$_2$O, 99.0%) and D$_2$O (99.9%) were obtained from Sigma-Aldrich, USA. Sodium hypochlorite solution (NaClO, available Cl 4.0%) was obtained from Shanghai MACKLIN Chemical Works, China. P-dimethylaminobenzaldehyde (PDAB, C$_9$H$_{11}$NO, 99%) was obtained from Adamas-beta Chemical Co., Switzerland. Nitrogen (N$_2$, high purity 99.999%) and argon (Ar, high purity 99.999%) were purchased from Ju’yang gas Co., China. $^{15}$N$_2$ (enrichment of > 99% atom $^{15}$N) was obtained from Shanghai Research Institute of Chemical Industry Co., China. All chemical were commercial and used without further purification. Ultrapure water (18.2 MΩ cm) was used in all experiments.

Preparation of NPG catalysts

The NPG catalysts were prepared using an electrochemical dealloying method in a standard three-electrode cell with a Pt gauze as the counter electrode and a Ag/AgCl
electrode as the reference electrode. The Au$_{35}$Ag$_{65}$ leaf (3 cm × 3 cm) was used as the work electrode and dealloyed in 0.1 M HNO$_3$ solution by using an electrochemical workstation with a dealloying potential of 1.307 V versus RHE. The obtained NPG samples were carefully rinsed with ultrapure water to remove residual acid and impurity ions. All electrochemical potentials were determined with respect to RHE using the equation (Eq. 1):

$$E_{\text{RHE}} = 0.198 + 0.059 \cdot pH + E(\text{Ag}/\text{AgCl})$$  

Microstructural and chemical characterization

The morphological and lattice structural information of the NPG samples were investigated with field emission SEM (FEI Nano430) and TEM (JEM-2100F) combined with an EDS. XPS was performed using Physical Electronics 5400 ESCA photoelectron spectrometer.

Electrochemical measurements

Before NRR test, the Nafion 115 membranes were heat-treated in 5.0 wt% H$_2$O$_2$ solution, 0.5 M H$_2$SO$_4$ solution, and ultrapure water for 1 h, respectively.$^1$ Electrochemical measurements were performed using a gas-tight two-compartment electrochemical cell separated by a piece of Nafion 115 membrane at room temperature. The Pt gauze and Ag/AgCl electrode were used as counter electrode and reference electrode, respectively. The work electrode was prepared by placing the NPG film onto glassy carbon electrode (0.07 cm$^2$). The linear sweep voltammetry was conducted at a scan rate of 20 mV/s. The electrocatalytic performance of NPG
catalyst for NRR was evaluated using controlled potential electrolysis in 0.1 M HCl aqueous solution for 2 h at room temperature (~25 °C). The electrolyte was presaturated with N\textsubscript{2} by N\textsubscript{2} gas bubbling for at least 30 min prior to each measurement. During the measurement, the electrolyte was continuously bubbled with N\textsubscript{2} at a flow rate of 10 sccm.

**Ammonia quantification**

The produced NH\textsubscript{3} was quantitatively determined by the indophenol blue method.\textsuperscript{2} Typically, 2.0 mL of the sample solution was first pipetted from the electrochemical reaction vessel. Afterwards, 2.0 mL of NaOH solution (1.0 M) containing C\textsubscript{7}H\textsubscript{6}O\textsubscript{3} (5.0 wt%) and C\textsubscript{6}H\textsubscript{5}Na\textsubscript{3}O\textsubscript{7} (5.0 wt%), 1.0 mL of NaClO solution (0.05 M), and 0.2 mL of C\textsubscript{3}FeN\textsubscript{6}Na\textsubscript{2}O solution (1.0 wt%) were added into the above solution. After 2 h, the absorption spectra of the resulting solution were acquired with an UV-vis spectrophotometer (Varian Cary 50). The obtained indophenol blue was measured by absorbance at \(\lambda = 656\) nm. In order to quantify the produced NH\textsubscript{3}, the calibration curve was built using standard NH\textsubscript{4}Cl solutions in the presence of 0.1 M HCl. The measurements with the background solutions (no NH\textsubscript{3}) were performed for all experiments, and the background peak was subtracted from the measured peaks of NRR experiments to calculate the NH\textsubscript{3} concentrations and the Faradaic efficiencies.

**Hydrazine quantification**

The produced N\textsubscript{2}H\textsubscript{4} was determined by the method of Watt and Chrisp.\textsuperscript{3} The color reagent was obtained by mixing 4.99 g of PDAB with 20 mL of concentrated
HCl and 200.0 mL of C\textsubscript{2}H\textsubscript{5}OH. And then 5.0 mL of the electrolyte solution was taken out and mixed with 5.0 mL of the above color reagent. After 15 min, the absorption spectra of the resulting solution were acquired using a UV-vis spectrophotometer. The N\textsubscript{2}H\textsubscript{4} solution with known concentrations in 0.1 M HCl were used as calibration standard, and the absorbance at \( \lambda = 458 \) nm was used to plot the calibration curve.

**Calculation of the Faradaic efficiency and NH\textsubscript{3} yield rate**

The Faradaic efficiency was calculated from the charge consumed for NH\textsubscript{3} production and total charge passed through the electrode during the electrolysis (Eq. 2):

\[
\text{Faradaic efficiency} = \frac{[3F \times (C_{NH3,N2} - C_{NH3,Ar}) \times V])/17Q}{Q} \tag{2}
\]

The NH\textsubscript{3} yield rate was calculated using the following equation (Eq. 3):

\[
\text{NH}_3 \text{ yield rate} = \frac{[(C_{NH3,N2} - C_{NH3,Ar}) \times V)]/(t \times m)}{t \times m} \tag{3}
\]

Where F is the Faradaic constant (96485 C mol\textsuperscript{-1}), \( C_{NH3} \) is the measured NH\textsubscript{3} concentration (\( \mu \)g mL\textsuperscript{-1}), V is the volume of the electrolyte, Q is the total charge passed through the electrode, t is the electrolysis time (2 h), and m is the metal mass of the catalyst (0.018 mg).

**Calculation method for the overpotential of NRR**

The NRR occurs at 0.06 V versus RHE theoretically, therefore the overpotential of NRR can be calculated via the following formula (Eq. 4):

\[
\text{Overpotential} = 0.06 \text{ V} - \text{E (V, versus RHE)} \tag{4}
\]
An isotopic labeling experiment using $^{15}\text{N}_2$ (enrichment of $>99\%$ atom $^{15}\text{N}$) as the feed gas was conducted to elucidate the activity origin of NPG. Before the electrochemical reduction procedure, the electrolyte was purged with high purity Ar to remove the $^{14}\text{N}$ in the electrolyte and saturated with $^{15}\text{N}_2$ for 30 min with the flow rate of 10 sccm. After $^{15}\text{NRR}$ for 2 h at $-0.1$ V versus RHE in 0.1 M HCl solution, the obtained $^{15}\text{NH}_4^+$ electrolyte was determined by 1H nuclear magnetic resonance (NMR, Bruker, Avance III 600 MHz). To prepare the NMR sample, 20 mL of electrolyte after NRR was concentrated to $\sim 1$ mL, then $30\mu$L of 100 ppm dimethyl sulfoxide-$d_6$ (DMSO-$d_6$) and $70\mu$L D$_2$O was added in the solution. Similarly, the amount of $^{14}\text{NH}_4^+$ was determined by this method when $^{14}\text{N}_2$ ($99.999\%$) was used as the feed gas. All NMR measurements were carried out with water suppression and 4000 scans.

**DFT calculation methods**

All DFT calculations were performed in the Dmol3 code with the spin polarization.$^5$ The generalized gradient approximation (GGA) with Perdew-Burke-Ernzerhof functional (PBE) was applied to describe the exchange-correlation effects.$^6$ The relativistic effects were implemented by DFT semicore pseudopotentials core treatment with the basis set of double numerical plus polarization (DNP).$^7$ For geometrical optimization, the convergence criteria of energy change, gradient, and displacement were $1.0 \times 10^{-5}$ hartree, $2.0 \times 10^{-3}$ hartree Å$^{-1}$, and $5.0 \times 10^{-3}$ Å, respectively. TS method for DFT-D correction was used to accurately describe the van der Waals forces.$^8$ The vacuum gap set to be about 15 Å, which should lead to negligible interactions between the system and their mirror images. The
computational hydrogen electrode (CHE) model was used for calculating the reaction processes.\textsuperscript{9} Thus, the reaction free energy ($\Delta G$) was determined by $\Delta G = \Delta E + \Delta ZPE - T \Delta S + \Delta G_U$, where $\Delta E$, $\Delta ZPE$, $T$, $\Delta S$, and $\Delta G_U$ indicated the reaction energy, zero point energy, temperature, change of entropy, and free energy contribution due to the electrode potential (U), respectively.
