## **Supporting Experimental Data**

**Figure S1.** <sup>19</sup>F NMR spectra of **2** treated with a) 0 equiv BCl<sub>3</sub>, b) 0.5 equiv BCl<sub>3</sub> and c) 1 equiv BCl<sub>3</sub>. Note the appearance of a new signal around -124 ppm that suggests the presence of an F-B-Cl BODIPY intermediate in the halogen exchange of **2** to **3**.

**Figure S2.** <sup>1</sup>H NMR spectra tracking the decomposition of **3** when exposed to ambient atmosphere. Bottom to top: before opening; immediately after opening; 30 min; 1 hour; 2 hours; 12 hours; 3 days. Note the appearance of signals at 14.4 and 8.5 ppm as decomposition progresses.

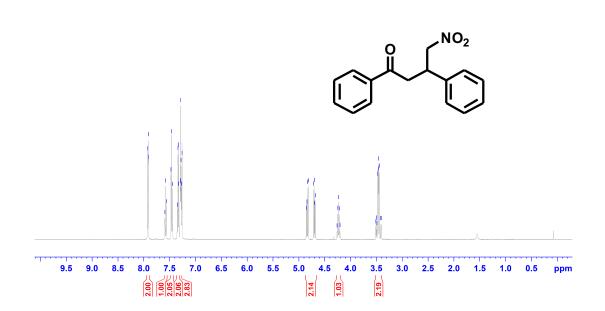

**Figure S3.** <sup>1</sup>H NMR (aromatic region) of **1** and its salts. Bottom to top: **1**, **1HCl**, **1HBr**, and **1HBF**<sub>4</sub>. Note the simplification of signal patterns upon protonation (i.e. **1** cf. **1HX**).

## **Crystallographic Data**

The crystals chosen for data collection were attached to the tip of a 200 µm MicroLoop with paratone-N oil. Measurements were made on a CCD-equipped diffractometer (30 mA, 50 kV) using monochromated Mo K $\alpha$  radiation ( $\lambda$  = 0.71073 Å) at 125 K.<sup>2</sup> The initial orientations and unit cells were indexed using a least-squares analysis of a random set of reflections collected from three series of  $0.5^{\circ}$   $\omega$ -scans, 10 seconds per frame and 12 frames per series, that were well distributed in reciprocal space. For data collection, four  $\omega$ -scan frame series were collected with 0.5° wide scans, 60 second frames and 366 frames per series at varying  $\phi$  angles ( $\phi = 0^\circ$ , 90°, 180°, 270°). Compounds **1HCI** and **1HBF**<sub>4</sub> required only 20 seconds per frame. The crystal to detector distance was set to 6 cm and a complete sphere of data was collected. Cell refinements and data reductions were performed with the Bruker SAINT<sup>3</sup> software, which corrects for beam inhomogeneity, possible crystal decay, Lorentz and polarisation effects. A multiscan absorption correction was applied in each case (SADABS).<sup>4</sup> The structures were solved using SHELXT-2014<sup>5, 6</sup> and were refined using a full-matrix least-squares method on F<sup>2</sup> with SHELXL-2014.<sup>5, 6</sup> The non-hydrogen atoms were refined anisotropically. Hydrogen atoms bonded to carbon were included at geometrically idealised positions and were not refined. The isotropic thermal parameters of the hydrogen atoms were fixed at  $1.2U_{eq}$  of the parent carbon atom or  $1.5U_{eq}$  for methyl hydrogens. The H(N) hydrogen atoms, if present, were allowed to refine isotropically. If necessary, a weak restraint was placed on the N-H bond length.

In the final refinement of compound **1HBr** enhanced rigid body restraints were applied over the entire molecule, using the RIGU command in SHELXL,<sup>5, 6</sup> to make the orientations of the atomic displacement parameters more reasonable.

The crystal structures of compounds **1HCl**, **1HBr** and **1HBF**<sub>4</sub> were all found to incorporate dichloromethane solvent from the crystallisation media. In the two former cases there was one half a solvent molecule in the asymmetric unit (or one molecule of solvent for each two cation/anion pairs) while in the latter case, one dichloromethane solvent molecule was found in the asymmetric unit (or one molecule of solvent for each taken the cation/anion pair). In **1HBF**<sub>4</sub> the solvent was not disordered and was well-behaved during the refinement. In **1HCl** and **1HBr** the solvent is disordered across the inversion centers of the unit cell. In **1HCl** it is well-behaved and did not have to be restrained during the refinement. In **1HBr** the C-Cl bond lengths were restrained to be approximately equal during the refinement.

All diagrams were prepared using the program Mercury CSD 3.7.<sup>7</sup> The data has been deposited with the Cambridge Crystallographic Data Centre. The deposition numbers for each compound are given in Table S1.

#### Table S1: Crystal data and structure refinement details.

N,N-Dichloroboryl-[N-(3-phenyl-2H-isoindol-1-yl)-N-(3-phenyl-1H-isoindol-1-ylidene)amine] (6)

Gold coloured, thin rectangular rods were grown via slow evaporation from dichloromethane under nitrogen atmosphere. The boron center is pseudo-tetrahedral (sum of angles 657.74°), and the relatively wide bite angle of 106.8(2)° agrees with bite angles typically observed in BODIPYs.<sup>1</sup> B-Cl bond lengths are long at ca. 1.8 Å, and substantially longer than the analogous *F*-aza-BODIPY (ca. 1.4 Å),<sup>8</sup> supporting the increased lability and facilitated nucleophilic substitution.

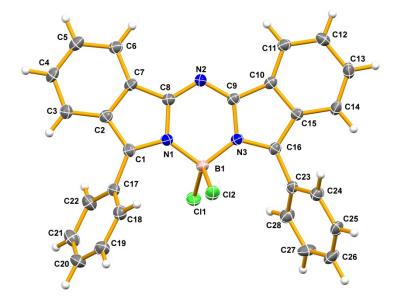

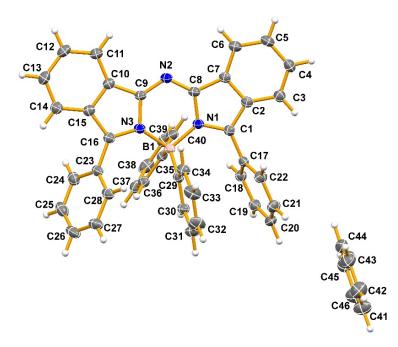

Figure S4. Structural diagram of 6. Thermal ellipsoids are drawn at 50% probability.

Bond	Length (Å)	Entry	Angle (°)
N1 – B1	1.549(4)	N1 – B1 – N3	106.8(2)
N3 – B1	1.553(4)	N1 – B1 – Cl2	111.69(19)
Cl1 – B1	1.848(3)	N3 – B1 – Cl2	107.95(18)
Cl2 – B1	1.847(3)	N1 – B1 – Cl1	107.89(18)
		N3 – B1 – Cl1	111.07(19)
		Cl2 – B1 – Cl1	111.34(16)

Table S2. Selected bond lengths and angles around boron of 6.

#### N,N-Diphenylboryl-[N-(3-phenyl-2H-isoindol-1-yl)-N-(3-phenyl-1H-isoindol-1-ylidene)amine] (8)

A dark green-black rough cube was cut from a thick rod (grown via slow evaporation from benzene) for data collection. The boron center is pseudo-tetrahedral (sum of angles 655.67°) with a somewhat wide bite angle in the expected range for BODIPYs,<sup>1</sup> but several degrees narrower than that of **6**. The C29 – B1 – C35 angle is wide (almost 120°), reasonably due to the steric demands of the phenyl substituents. The crystal is stabilised by  $\pi$ -stacking interactions (Figure S5), and thus crystallised easily from evaporating benzene.

**Figure S5a.** Structural diagram of **8**, including one molecule of benzene solvation. Thermal ellipsoids are drawn at 50% probability.

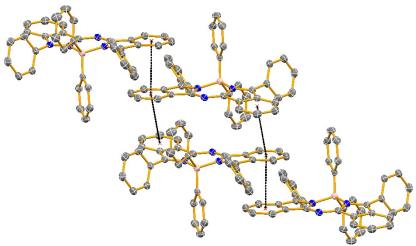

Figure S5b. Short ring stacking interactions within the crystal of 8.

Table S3. Selected bond lengths and angles around boron of 8.

Length (Å)	Entry	Angle (°)
1.5935(16)	N1 – B1 – N3	103.24(9)

	1.5935(16) 1.6201(16) 1.6152(18)	1.5935(16)         N1 - B1 - N3           1.6201(16)         N1 - B1 - C29           1.6152(18)         N3 - B1 - C29           1.6214(18)         N1 - B1 - C35           N3 - B1 - C35

#### N-(3,5-Diphenyl-2H-pyrrol-2-ylidene)-3,5-diphenyl-1H-pyrrol-2-amine hydrochloride (1HCl)

A clear, green rectangular prism was cut from a larger needle for data collection. The structure was found to contain one half of a dichloromethane solvent molecule in the asymmetric unit (or one molecule of solvent for each two cation/anion pairs). The crystal structure shows that the  $\alpha$ -phenyl rings are virtually completely coplanar with the dipyrrin core, while the  $\beta$ -phenyl rings are rotated slightly away from the plane of the core. This makes the overall structure of the compound appear very flat, leading to a sheet-like arrangement of constituents in the macroscopic lattice (Figure S7). The chloride ion is positioned centrally in the pocket defined by the pyrrolic nitrogen atoms and  $\alpha$ -phenyl rings (Figure S6a), and so planarity is induced via hydrogen bonding between Cl1 and N2H and N3H (Table S4 and Figure S7b) as well as between C10-H10 and Cl1. A similar effect is observed frequently in  $\alpha$ -aryl F-BODIPYs, where hydrogen bonding between the *ortho*-H of the  $\alpha$ -phenyl and the fluorine atoms of the contribution to non-radiative decay. Indeed, this effect is responsible for the moderate fluorescence quantum yield of **2** and similar *F*-aza-BODIPYs, where otherwise the free rotation of the four (or more) pendant arenes would lead to significant excited-state energy loss.

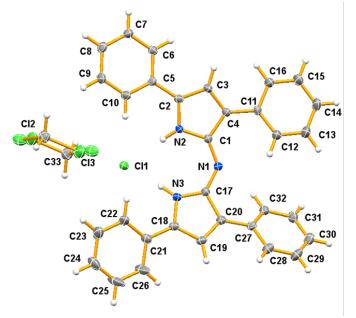

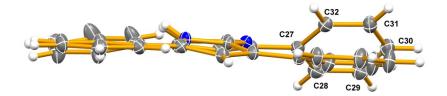

Figure S6a. Structural diagram of 1HCl. Thermal ellipsoids are drawn at 50% probability.

**Figure S6b.** Side-on view of **1HCI** highlighting co-planarity of  $\alpha$ -phenyl rings with the dipyrrin core, while the  $\beta$ -phenyls are further out of plane.

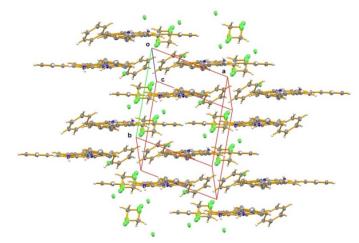

Figure S7a. Packing diagram of 1HCl drawn to illustrate the packing of the cation layers.

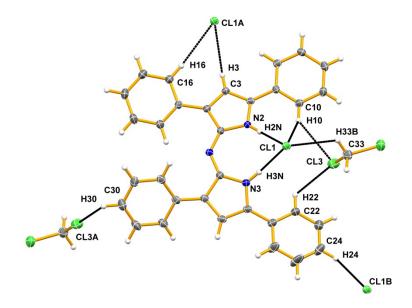

Figure S7b. Diagram of 1HCl showing the N-H...Cl and C-H...Cl hydrogen bonds in the structure.

#### N-(3,5-Diphenyl-2H-pyrrol-2-ylidene)-3,5-diphenyl-1H-pyrrol-2-amine hydrobromide (1HBr)

A dark green, thin flat needle was cut down for the data collection. The structure was found to contain one half of a dichloromethane solvent molecule in the asymmetric unit (or one molecule of solvent for each two cation/anion pairs).

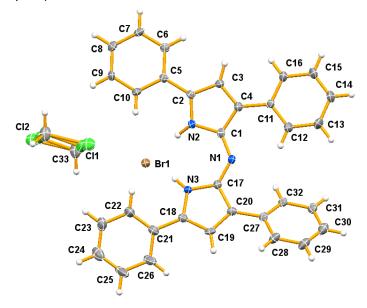

Figure S8. Structural diagram of 3HBr including solvent. Thermal ellipsoids are drawn at 50% probability.

#### N-(3,5-Diphenyl-2H-pyrrol-2-ylidene)-3,5-diphenyl-1H-pyrrol-2-amine hydrofluoroborate (1HBF<sub>4</sub>)

A dark green rectangular plate was chosen for the data collection. The structure was found to contain one dichloromethane solvent molecule in the asymmetric unit (or one molecule of solvent for each cation/anion pair).

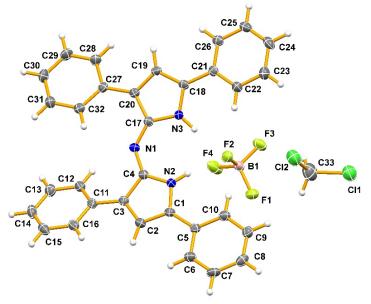

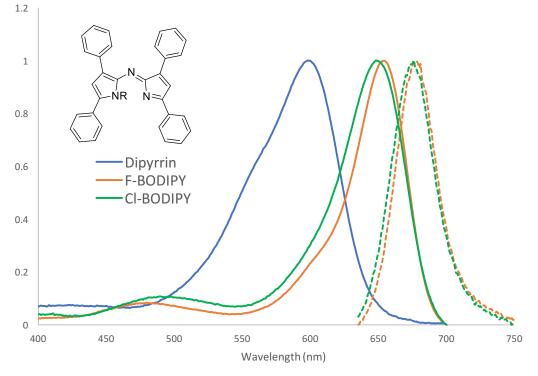

Figure S9. Structural diagram of 1HBF<sub>4</sub> including solvent. Thermal ellipsoids are drawn at 50% probability.
