## Methods:

### Model set-up:

Our model set-up follows previously reported methods and will be briefly summarised here.<sup>1</sup> We started our work from the 1LG9 protein databank (pdb) file, which is a P450 monomer of the resting state structure of OxyB. The docking of the prepared substrate with the OxyB was carried out using AutoDock Vina 4.0v.<sup>2</sup> The UCSF Chimera software<sup>3</sup> was used for visualizing the various docking poses and we selected the most stable substrate-bound structure. Subsequently, hydrogen atoms were added in Chimera. The model was based on the active site of the 1LG9 pdb structure with residues selected as highlighted in Scheme S1 below. We took the heme and replaced all side chains by hydrogen atoms except propionate group A, which was included in the model. The axial cysteinate (Cys<sub>347</sub>) was abbreviated to methylmercaptate and the resting state iron(III)-(water)heme replaced by iron(IV)-oxo heme cation radical or Compound I. The substrate binding pocket was described through the chains Leu<sub>235</sub>-Ala<sub>236</sub>-Gly<sub>237</sub>-Asp<sub>238</sub>-Asp<sub>239</sub>-Asn<sub>240</sub>-Ile<sub>241</sub> with Asp<sub>238</sub> abbreviated to Gly. In addition, the following groups were part of the model: namely, dimethylsulfide for Met<sub>55</sub> and the small chain Gln<sub>232</sub>-Val<sub>233</sub> and Pro<sub>286</sub>. The complete model had a total number of atoms of 258 and was calculated in the doublet and quartet spin states.

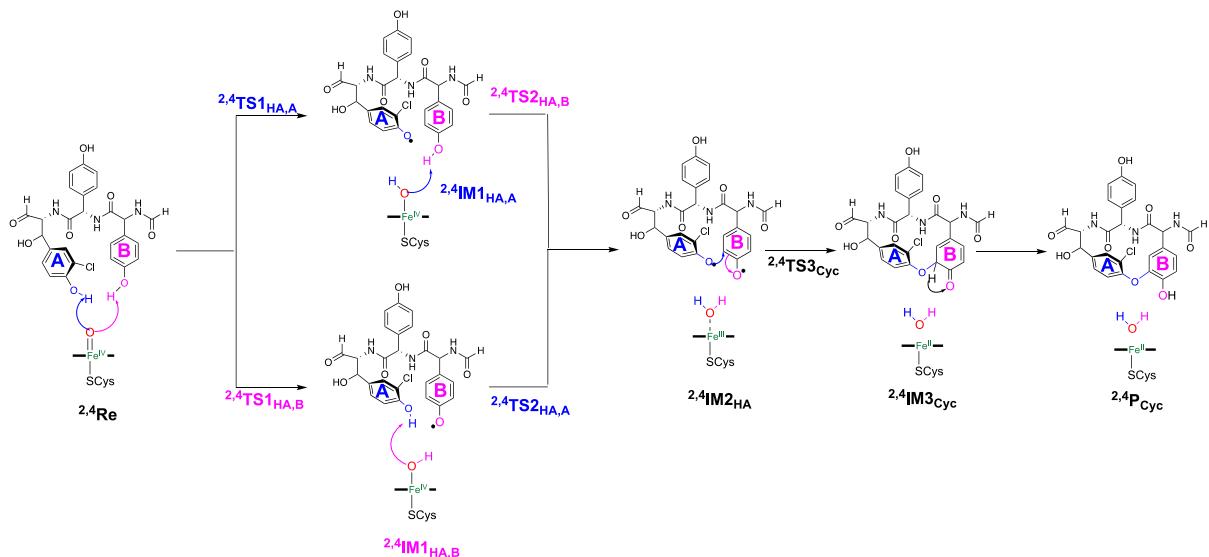

**Fig. S1:** Active site model of substrate bound complex of OxyB taken from the pdb file.

### Computational methods:

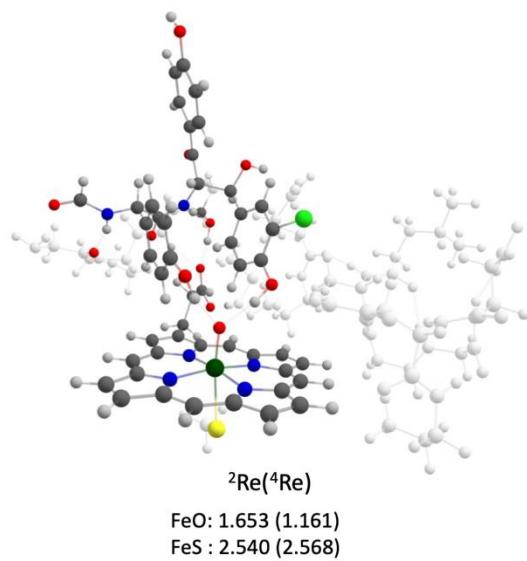

All the quantum mechanical calculations were done using density functional theory (DFT) methods which are implemented in Gaussian-09.<sup>4</sup> In previous work we extensively tested and benchmarked models and methods for P450 reaction mechanisms and reproduced experimental structures and rate constants well.<sup>5, 6</sup> All calculations used the unrestricted B3LYP hybrid density functional method,<sup>7</sup> in combination with a basis set containing an LANL2DZ + ECP on iron and 6-31G\* on the rest of the atoms (basis set BS1).<sup>8</sup> Full geometry optimizations, frequencies and scan calculations were run for all structures using UB3LYP/BS1 in the gas-phase. Subsequent single point calculations with the polarized continuum model (CPCM)<sup>9</sup> were performed with a dielectric constant mimicking chlorobenzene, and a triple- $\zeta$  quality basis set (basis set BS2) containing LACV3P+ + ECP on iron and 6-311+G\* on the rest of the atoms.
