## **Supplementary information**

**Figure S1**: A schematic diagram of the ellipsometric model used for\_polymer brushes swollen in water. Each layer (*z*) is equal in thickness but has a different density of polymer ( $\varphi$ ) within it. These values can be used to calculate the brush thickness ( $h_{wet}$ ) of polymer within the solution using Eq. 1. The equations used to derive the wet thickness can be found in the experimental section.

**Figure S2:** Representative AFM images taken over a 2500  $\mu$ m<sup>2</sup> area to gather data for both the average roughness and root mean square roughness, shown in Table 3.1, for samples (**A**) CuBr<sub>2</sub> catalyst source in deionised water, (**B**) CuBr<sub>2</sub> catalyst source in tap water, (**C**) Copper wire catalyst source in deionised water and (**D**) Copper wire catalyst source in tap water.

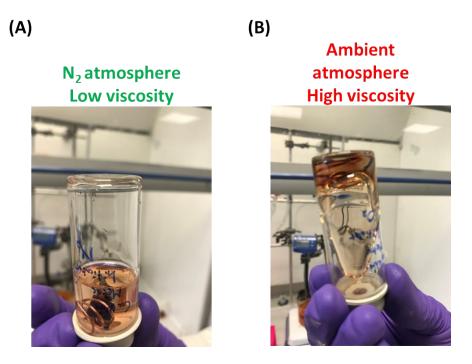

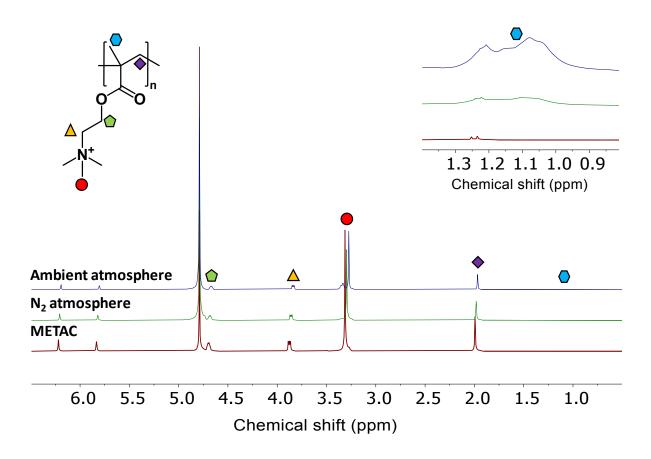

Figure S3: Images show the difference in viscosity of the monomer solution after 24 hours for (A) a solution degassed with nitrogen and left under nitrogen pressure and (B) a solution that was not degassed and left in ambient conditions.

**Figure S4:** <sup>1</sup>H NMR spectra of METAC monomer solution taken after 24 hours. The METAC solution was mixed with BPY, Ascorbic acid and added to tubes that contained 10 cm of copper wire. A broad peak is observed at 1.0 to 1.3 indicative of polymerisation due to a Fenton-type reaction. A control of METAC monomer is shown with no polymer peak.
