## 1. Evaluation of squaramides and thioureas on the Michael addition

A study between the diastereomeric squaramides **1a** and **S1a** showed that **1a** had the correct combination of stereochemistry between the cyclohexane and the tetrahydronaphthyl fragments (Scheme S1).

**Scheme S1.** Catalytic activity evaluation of diastereoisomeric squaramides.

The modeled geometries of these catalysts showed a structural difference: the phenyl ring in **1a** is on the same side as the diamino group whereas in the diastereoisomeric **S1a** catalyst it is on the opposite side (Figure S1). This difference establishes the better catalytic performance of the squaramide **1a** due to the occurrence of the non-covalent interactions discussed in the main body of the paper. This behavior has also been observed for thioureas.<sup>1</sup>

**Figure S1.** Top view of diastereoisomeric catalysts, left **1a** and right **S1a**.

**Scheme S2.** Catalysts screening (**1** and **S2**) on the Michael addition of 2,4-pentanedione to *trans*-β-nitrostyrene. Yields and ee for squaramides **1** and **S2** are shown in brown and in orange within parentheses, respectively. The reactions were performed on a 0.25 mmol scale of *trans*-β-nitrostyrene, 2 eq. of 2,4-pentanedione, 0.75 mL of solvent and a catalytic load of 1 mol% for squaramides and 5 mol% for thioureas catalysts. \*ref 1a, \*\*ref 1b.

## 2. Calculation of parameters and Multivariate Linear Regression model

### 2.1. General considerations

Geometry optimizations, frequency calculations and the computation of all the necessary parameters were carried out using the Gaussian 09 software, Revision D.01<sup>2</sup> at the B97-D/def2-TZVP<sup>3</sup> level of theory. All of the optimized geometries were confirmed by frequency computations as local minima (zero imaginary frequencies), except for the optimized geometries with a frozen dihedral angle ( $\alpha = 39.30^\circ$ ). Structural representations were generated with CYLview.<sup>4</sup> Multidimensional regression analyses were performed using Excel<sup>®</sup>.

### 2.2. Calculation of $E_C$ parameters

The modeled TS of thioureas **S2a** and **S2b** are almost superimposable and had a similar dihedral angles  $N_{(1)}-C-C_{(ipso)}-C_{(ortho)}$  ( $\alpha$ ). We found that the optimized geometry of the thiourea **S2a** is closer to the conformation in the TS, due to the conformational rigidity of the tetrahydronaphthyl group. (Figure S2).<sup>1b</sup>

**Figure S2.** (Left) Superimposable transition states for thioureas **S2a** and **S2b**. (Right) Optimized thiourea **S2a** in the basal state. XYZ coordinates reported in ref 1b.

Hence, we considered that squaramides **1** with different benzyl (and benzyl-like) substituents would present a TS with a similar “active conformation” that allows the formation of  $CH\cdots\pi$  interactions. This arrangement can be evaluated by the dihedral angle  $\alpha$ . The value found in the modeled geometry of **1a** ( $\alpha = 39.30^\circ$ ) could be very similar to the optimum value. Therefore, from the most stable local minima, we fix the dihedral angle  $\alpha$  to the active conformation and measure the difference in energy and label it as  $E_C$ . We followed the next protocol to compute the  $E_C$  parameter:

- We optimized the lowest energy conformer (**A**) of each catalyst and we confirmed the occurrence of a local minimum by frequency calculations.
- The geometry of each catalyst (except **1a**) was optimized with frozen dihedral angle  $\alpha = 39.30^\circ$  to look for a new conformer (**B**).
- The energy difference between both conformers defines  $E_C$  parameter ( $E_C = E(B) - E(A)$ ).

NOTE: When two conformers of the complexes are possible due to the presence of *ortho* or *meta* substituents on the phenyl ring, two  $E_C$  values were calculated. Both values were weighted according to the protocol established in section 2.3 (only conformers within an  $E_C$  value less than of 2.0 kcal/mol were considered).

The geometries of the conformers used to determine the  $E_C$  parameter are shown in Figure S3.

**Figure S3.** Conformers of the catalysts with their respective values of  $E_C$ .

**Figure S3 (continuation).** Conformers of the catalysts with their respective values of  $E_C$ . We considered  $\alpha = 39.30^\circ$  for all the B-conformers.

### 2.3. Calculation of $\pi$ -parameters

The B-rotamer of the catalysts is the active conformation to form  $\text{CH}\cdots\pi$  interactions. Thus, we considered this rotamer to determine  $\pi$ -parameters following the Sigman's protocol:<sup>5</sup>

- The separate components P (probe) and Cat (squaramide catalyst) of the complex were optimized at the B97D/def2TZVP level of theory. The energies of these components were labeled as  $E_P$  and  $E_{Cat}$ .
- The components P and Cat were placed together in such a way that form  $\text{CH}\cdots\pi$  interactions (see Figure S4). The geometry is fixed and the distance between the centroids of the rings ( $x$ ) is scanned (steps of  $0.05 \text{ \AA}$ ) to obtain the energy ( $y$ ) of the complex.
- The obtained curve is fitted with a fourth degree polynomial function ( $ax^4 + bx^3 + cx^2 + dx + e = y$ ).
- The roots of the polynomial were calculated using the function roots in Matlab<sup>®</sup> and the array corresponding to the derivative of the polynomial. The stationary point corresponding to the energy minimum is defined as the interaction distance  $D\pi$ .
- The substitution of  $D\pi$  in the original polynomial function renders the minimum energy of the complex  $E_{Comp}$  ( $aD\pi^4 + bD\pi^3 + cD\pi^2 + dD\pi + e = E_{Comp}$ ).
- Finally, the interaction energy  $E\pi$  is calculated using the formula  $E\pi = E_{Comp} - E_P - E_{Cat}$ .

- B-conformer of the catalysts and benzene were used as a probe.
- **A** center of the probe arene.
- **C** center of the catalyst arene.
- Angle **ABC** =  $180^\circ$ .
- The plane **abc** is perpendicular to the line **BC**.
- The dihedral angle **aCBD** =  $0^\circ$ .
- The variable  $x$  is defined as the distance **AC**.

**Figure S4.** Geometrical requirements for the calculation of  $\pi$ -parameters.

When two conformers of the complexes can coexist due to the presence of *ortho* or *meta* substituents on the aryl ring, two  $D\pi$  and two  $E\pi$  values were computed.  $D\pi_d$  and  $D\pi_D$  are defined as the distances relative to the complexes with the lowest and highest  $D\pi$ , respectively. In the same fashion,  $E\pi_d$  and  $E\pi_D$  are the interaction energies corresponding to the complexes with distances  $D\pi_d$  and  $D\pi_D$ , respectively.  $D\pi_w$  and  $E\pi_w$  are the energy-weighted interaction distance and energy calculated with equation 1. Only conformers within an energy range of 2.0 kcal mol<sup>-1</sup> were considered. The importance of each conformer is quantified by the coefficients  $c_x$ , which are calculated according to the Boltzmann distribution over the two considered conformers (equation 2).

$$P_w = c_d P_d + c_D P_D \quad \text{Equation 1}$$

where  $P$  is the parameter to study ( $E\pi$ ,  $D\pi$ ,  $E_c$ ,  $\omega$ , etc.)

$$c_x = \frac{\exp[-E\pi_x/RT]}{\exp[-E\pi_d/RT] + \exp[-E\pi_D/RT]} \quad \text{Equation 2}$$

where  $X = d, D$

The structures of the  $\pi$ -complexes with their interaction energies and distances values are shown in Figure S5.

**Figure S5 (continuation).** Complexes used to determine  $\pi$ -parameters.

#### 2.4. Other parameters collected.

Other steric parameters were determined using the B-conformer of the catalysts. In particular, we calculated sterimol<sup>6</sup> parameters for the aryl and benzyl groups, B-conformer of the squaramide **1i** is described as a graphical example in Figure S6.

**Figure S6.** Sterimol parameters for aryl (left) and benzyl (right) moieties. For symmetrical aryl moieties  $B1_{\text{Ar}}$  and  $B5_{\text{Ar}}$  have the same value. Benzyl moiety is shown in Newman perspective.

$L_{\text{Ar}}$ ,  $B1_{\text{Ar}}$  and  $B5_{\text{Ar}}$  are the length, minimum width and maximum width of the aryl group, respectively. In the same way,  $B1_{\text{Bn}}$  and  $B5_{\text{Bn}}$  are the minimum width and maximum width of the whole benzyl group.

The dihedral angles were measured from the optimized structures as shown in the Figure S7.

**Figure S7.** Geometrical parameters

Finally, to establish a linear free-energy relationship we measured indirectly  $\Delta\Delta G^\ddagger$  from the experimental enantiomeric ratio (er). We used the formula  $\Delta G^\ddagger = [-RT \ln(\text{major enantiomer})] - [-RT \ln(\text{minor enantiomer})]$  where  $R$  is the ideal gas constant, and  $T$  is temperature (293.15 K). Table S1 shows er and  $\Delta\Delta G^\ddagger$  values as well as the values of all parameters computed.

## 2.5. Multivariate linear regression model

We found a single correlation with a qualitative agreement between  $E_C$  parameter and  $\Delta\Delta G^\ddagger$  was found ( $R^2 = 0.518$ , Figure S8, left). On the other hand, the cross-term  $E\pi E_C$  showed a correlation with  $R^2 = 0.561$  (Figure S8, right).

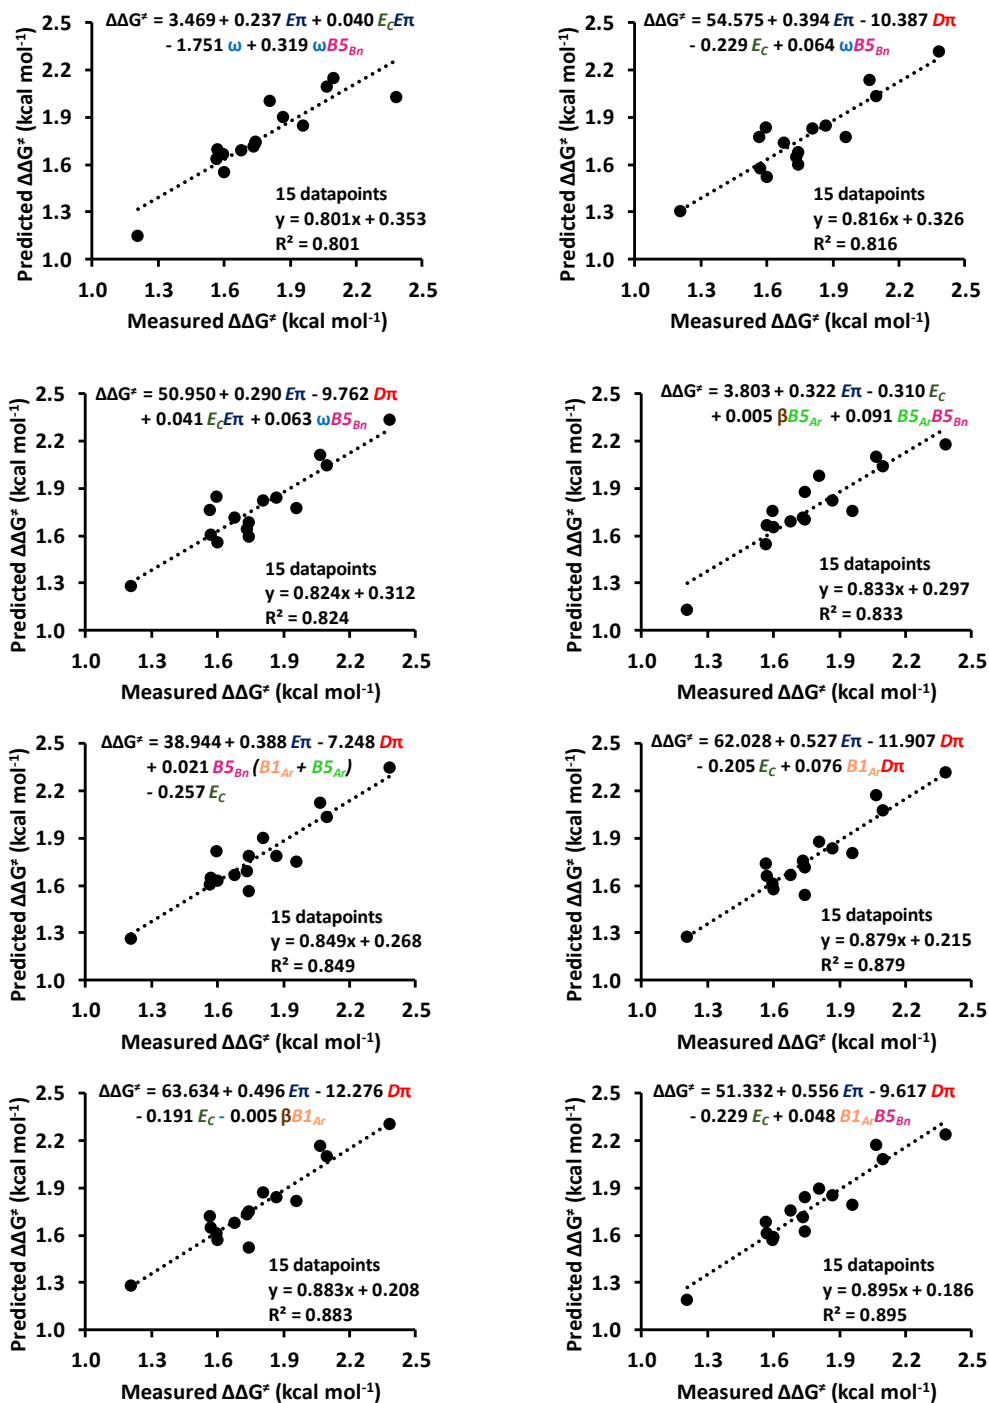

**Figure S8.** Single correlations between  $\Delta\Delta G^\ddagger$  with  $E_C$  (left) and  $E\pi E_C$  (right).

Multiple linear regression models were developed using the Data Analysis ToolPack in Excel®, some models are represented in (Figure S9).

**Figure S9.** Representative MLR models involving  $\Delta\Delta G^\ddagger$ .

**Figure S9 (continuation).** Representative MLR models involving  $\Delta\Delta G^\ddagger$ .

After several attempts we found three possible MLR models that could explain the behavior of the catalysts (Figure S10). A good linear correlation between the Predicted  $\Delta\Delta G^\ddagger$  and the Measured  $\Delta\Delta G^\ddagger$  indicates that the models adequately describe the system under study. The validation of the models (leave-one-out L1O and leave-two-out L2O cross-validation) was a decisive factor in choosing between one model or another. L1O- and L2O-values close to  $R^2$  prove the statistical robustness of the model. Thus,

we employed the model in Figure S10b (Figure 3 in the manuscript) to continue with our study. This model predicts well the behavior of most of the catalysts. The equation is composed of four terms:  $E_{\pi}$  and  $D_{\pi}$  describes the strength of the NCI, the term  $E_c E_{\pi}$  is related with conformational effects, and the cross-term  $\beta B1_{Ar}$  accounts for geometrical/steric requirements.

## 2.6. Other non-covalent interactions

When we analyzed the  $\pi$ -parameters for **1o**, we found a distance  $d_{H,F} = 2.73 \text{ \AA}$  between the squaramide and the probe (Figure S12). This value is consistent with CH $\cdots$ FC interactions.<sup>7</sup> That kind of interaction could be present in the TS of the Michael addition catalyzed by **1o**.

## 5. Transition states modeling and quantum chemical topology analyses

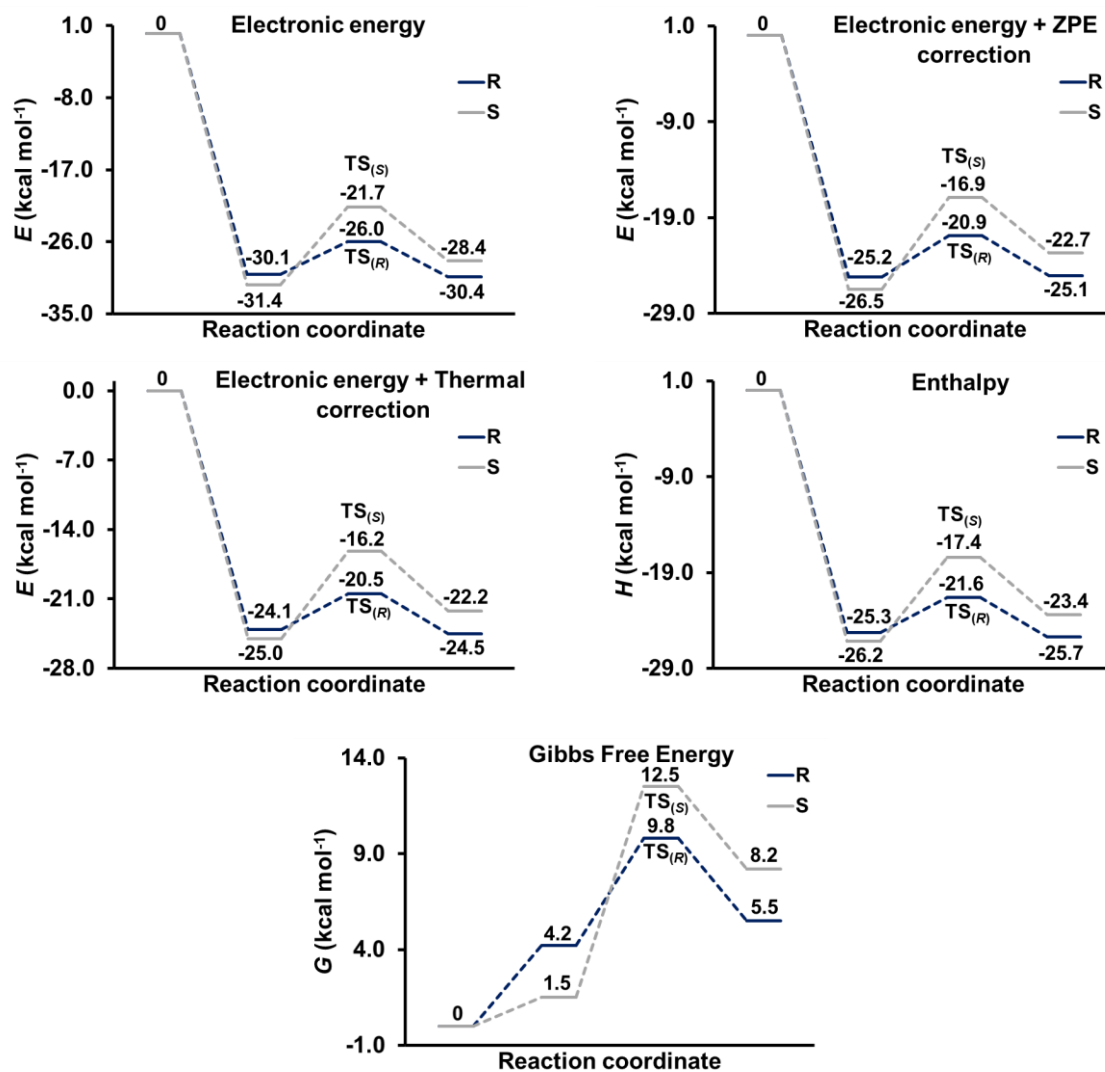

### 5.1. General considerations

The geometry of all intermediates and transition states were completely optimized with the PCM-(toluene)-B97-D/TZVP<sup>1,8</sup> approximation as implemented in the Gaussian 16, Revision C.01<sup>9</sup>. Structural representations were generated with the package CYLview.<sup>4</sup> Each stationary structure was characterized as a local minimum or a saddle point of first order through the computation of the corresponding harmonic frequencies. Intrinsic reaction coordinate calculations were carried out in all cases to verify that the localized transition state structures connect the two minima on the potential energy surface associated with reactants and products. Single-point energy calculations on the optimized geometries were then evaluated using the same functional (B97-D) and the triple-zeta valence quality def2-TZVP basis set, within the PCM model (toluene). Thermal corrections were calculated from the unscaled vibrational frequencies at the B97-D/TZVP level on the optimized geometries.

The topological analyses of the electron density determined with the method (PCM-(toluene)-B97D/TZVP) were done in accordance with the Quantum Theory of Atoms in Molecules (QTAIM) implemented in the AIMAll<sup>10</sup> program. The QTAIM characterization was done in terms of the properties of electron density  $\rho(\mathbf{r})$ , the delocalization indexes (DIs), and the hydrogen bond energy according to the Espinosa estimation  $E_H$ .<sup>11</sup> All local topological descriptors are computed at intermolecular bond critical points. The IQA energy partition was performed with M06-2x/TZVP//PCM(toluene)-B97-D/TZVP electron densities to get further insights about the chemical bonding of the examined transition states. The IQA calculations were carried out with the AIMAll<sup>10</sup> program.

### 5.2. Rate-limiting step computation of the Michael addition

The rate of the organocatalyzed addition of 2,4-pentanedione to  $\beta$ -nitrostyrene is determined by the formation of the C-C bond. This step is also responsible for the enantioselectivity of the reaction. Therefore, and to understand in more detail the origins of the stereoselectivity, we computed this reaction path with the PCM-(toluene)-B97-D/def2-TZVP//PCM-(toluene)-B97-D/TZVP level of theory. Energy profiles and theoretical activation barriers are shown in Figure S15 and Table S4, respectively.

**Figure S15.** Profiles of relative energies to reactants for the Michael reaction under consideration with catalyst **1a**. The full description of the approximation and basis set is: PCM-(toluene)-B97-D/def2-TZVP//PCM-(toluene)-B97-D/TZVP. The values are reported in kcal mol<sup>-1</sup>.

### 5.3. Analysis of the transition states by Quantum Theory of Atoms in Molecules (QTAIM)

We performed the QTAIM analysis to quantify and recognize the interactions involved in the transition states to generate the *R*- and *S*-products through the reaction with the catalyst **1a**. According to QTAIM data (Table S5), the TS<sub>(R)</sub> exhibits stronger interactions than its counterpart TS<sub>(S)</sub>, e.g. H<sub>2</sub>⋯O<sub>2</sub> and H<sub>3</sub>⋯O<sub>3</sub>. Additionally, the formation of the *R*-product yields a bifurcated hydrogen bond among H<sub>1</sub>, H<sub>2</sub> and O<sub>1</sub> atoms, which is not present in TS<sub>(R)</sub>. Those interactions in the former TS are stronger than they are in latter as indicated by the electron density  $\rho(\mathbf{r})$ , delocalization indexes (DIs) and hydrogen bond energies ( $E_{\text{HB}}$ ) values, which are descriptors related to the strength of the association. The magnitude of  $E_{\text{HB}}$ , indicates that H⋯O contacts are stronger in the formation of TS<sub>(R)</sub> than in the generation of TS<sub>(S)</sub>. This trend of HB strength is also observed for electron density and DIs values.

#### 5.4. Interacting quantum atoms energy partition

The Interacting Quantum Atoms (IQA) method is an electronic energy partition,  $E$ , in one ( $E_{net}^A$ ) and two atoms ( $E_{int}^{A\cdots B}$ ) terms<sup>12</sup> as indicated in Equation 3.

$$E = \sum_A E_{net}^A + \sum_A \sum_{B>A} E_{int}^{A\cdots B}, \quad \text{Equation 3}$$

where the sums run over atomic regions.  $E_{net}^A$  and  $E_{int}^{A\cdots B}$  are designated as (i) the IQA net energy of atom  $A$  and (ii) the IQA interaction energy between two atoms,  $A$  and  $B$ .<sup>13</sup> IQA energies can be calculated using the QTAIM spatial partition with DFT electron densities, using the same program (AIMAll).<sup>10</sup> This approach yields the total DFT electronic energy according to equation 3. Considering that the IQA approach is invariant with respect to the assembly of QTAIM atoms in molecules, the energy of a trimolecular complex

Where *Cat* = catalyst, *Nuc* = nucleophile and *Elec* = electrophile.

can be written as

$$\Delta E = E^{Cat \cdots Nuc \cdots Elec} - (E_{iso}^{Cat} + E_{iso}^{Nuc} + E_{iso}^{Elec}). \quad \text{Equation 5}$$

This equation can be rewritten as follows

$$\Delta E = \sum_{species} E_{def}^{species} + E_{int}^{Cat \cdots Nuc} + E_{int}^{Cat \cdots Elec} + E_{int}^{Nuc \cdots Elec}, \quad \text{Equation 6}$$

where

$$E_{def}^{species} = E_{net}^{species} - E_{iso}^{species} \quad \text{Equation 7}$$

$E_{def}^{species}$  is related to the changes of the electron density and the nuclear geometry associated with the interaction of monomer (*Cat*, *Nuc* or *Elec*) with other molecules and  $E_{iso}^{species}$  denotes the energy of the isolated species.

We can write  $\Delta E$  as pairwise contributions

$$\begin{aligned} \Delta E = & \left\{ E_{int}^{Cat \cdots Nuc} \left[ 1 + \left( \frac{E_{def}^{Cat}}{E_{int}^{Cat \cdots Nuc} + E_{int}^{Cat \cdots Elec}} \right) + \left( \frac{E_{def}^{Nuc}}{E_{int}^{Nuc \cdots Cat} + E_{int}^{Nuc \cdots Elec}} \right) \right] \right. \\ & + E_{int}^{Cat \cdots Elec} \left[ 1 + \left( \frac{E_{def}^{Cat}}{E_{int}^{Cat \cdots Nuc} + E_{int}^{Cat \cdots Elec}} \right) + \left( \frac{E_{def}^{Elec}}{E_{int}^{Elec \cdots Cat} + E_{int}^{Elec \cdots Nuc}} \right) \right] \\ & + E_{int}^{Nuc \cdots Elec} \left[ 1 + \left( \frac{E_{def}^{Nuc}}{E_{int}^{Nuc \cdots Cat} + E_{int}^{Nuc \cdots Elec}} \right) \right. \\ & \left. \left. + \left( \frac{E_{def}^{Elec}}{E_{int}^{Elec \cdots Cat} + E_{int}^{Elec \cdots Nuc}} \right) \right] \right\}, \quad \text{Equation 8} \end{aligned}$$

Furthermore,  $E_{int}^{M \cdots N}$  term can be divided into

$$E_{int}^{M\cdots N} = E_{Class}^{M\cdots N} - E_{XC}^{M\cdots N}$$

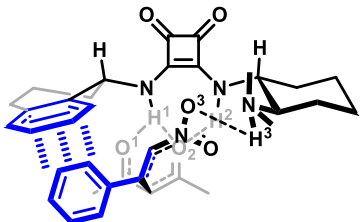

**Equation 9**

$E_{Class}^{M\cdots N}$  is the electrostatic component and  $E_{XC}^{M\cdots N}$  is the exchange-correlation term, which are the ionic and covalent contributions of the interactions between  $M$  and  $N$ , respectively.

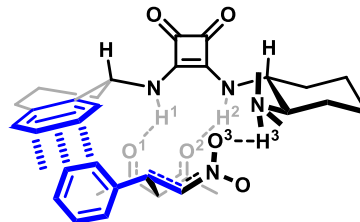

Deformation energies of *Cat*, *Nuc* and *Elec* were considered to obtain the IQA pairwise contributions to  $\Delta E$  (presented in Table 4 of the manuscript), while Table S5 shows the IQA total interaction energies of the relevant Non-Covalent Interactions involved in the diastereomeric transition states.

In Table S6, the analysis exposed that the formation energy in  $TS_{(R)}$  (-29.5 kcal mol<sup>-1</sup>) is superior to that in  $TS_{(S)}$  (-20.8 kcal mol<sup>-1</sup>). This difference arises because of the coupling between catalyst **1a** and the electrophile as well as the interaction electrophile...nucleophile which are stronger in the  $TS_{(R)}$ . Interestingly, the interaction energy shows that the covalence between electrophile...nucleophile is higher in *R* than in *S*, which may indicate that the formation of the C-C bond is better in the first case. In general terms, the HBs present in the  $TS_{(R)}$  are greater in number and strength, which agrees with the topological data in Table S5 for these interactions (Table S7). On the other hand, a stronger  $\pi$ -interaction is present in  $TS_{(R)}$ . Something to highlight is that the coulombic component has a greater impact on  $TS_{(R)}$  than on  $TS_{(S)}$ , which may be due to the proximity between the phenyl rings. In conclusion, the data obtained by IQA showed that  $TS_{(R)}$  is a reactive specie of low energy (compared to  $TS_{(S)}$ ), in this way the activation barrier decreased, and the reaction is highly selective. These computational results agree with the experimental data obtained.

## 6. Experimental procedures for the synthesis of bifunctional organocatalysts and its evaluation in Michael additions

### 6.1. General methods

Starting materials were purchased from Sigma-Aldrich and used as received. Reactions were monitored by thin-layer chromatography (TLC) on silica gel plates F254 and the spots were detected either by UV absorption, Seebach's stain or  $\text{KMnO}_4$ . Flash column chromatography was carried out with silica gel 60 (0.4/0.63 mm, 230-400 mesh).  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded at ambient temperature using Bruker Fourier-300 MHz, Jeol Eclipse-300 MHz, and Bruker Avance III-400 MHz spectrometers. Chemical shifts ( $\delta$ ) are reported in ppm relative to residual solvent signals ( $\text{CDCl}_3 = \delta$  7.26 for  $^1\text{H}$  NMR,  $\delta$  77.16 for  $^{13}\text{C}$  NMR.  $\text{DMSO}-d_6 = \delta$  2.50 for  $^1\text{H}$  NMR,  $\delta$  39.52 for  $^{13}\text{C}$  NMR) or TMS as internal reference ( $\delta$  0.0) and coupling constants are in hertz (Hz). Mass spectra were obtained by direct analysis in real time (DART) in a JEOL AccuTOF JMST100LC spectrometer with TOF mass analyzer. CSP-HPLC analyses were performed using the indicated chiral column and UV detector. The FT-IR spectral data were recorded in a Bruker ATR in the 450-4000  $\text{cm}^{-1}$  range. Uncorrected melting points were determined in a Fisher Johns melting point apparatus. Catalysts **1i**<sup>14</sup> and **1o**<sup>15</sup> used in this work were synthesized according to the reported procedures.

The reaction mixture was then stirred under reflux for 24 h, basified with 6 M aqueous NaOH to pH 12 and extracted three times with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic layers were dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtrated and concentrated in vacuo. The residue was purified by recrystallization from MeOH to give the respective compound.

### 6.3. Michael additions

**General procedure for conjugate addition reactions.** To a solution of nitrostyrene (0.25 mmol) and the respective organocatalyst (1.0 mol%) in toluene (0.76 mL) was added 1,3-dicarbonyl compound (0.50 mmol). After 24 hours the reaction mixture was concentrated and purified by flash chromatography with a mixture of hexane/EtOAc (7:3) to afford the conjugate addition product.
