**Figure S7.** Complete magnetic-field-variable alternate-current (*ac*) magnetic susceptibility characteristics of **HL3-Dy** at  $T = 1.8$  K, under  $H_{ac} = 1$  Oe, and their analysis: frequency dependences of the out-of-phase susceptibility,  $\chi_M''$  (a), and the in-phase susceptibility,  $\chi_M'$  (b) at various indicated *dc* external magnetic fields, together with the related Argand plots (c), and the field dependence of the relaxation time,  $\tau$  (d). Both field and relaxation time were presented in (d) in the logarithmic scale. Coloured solid curves in (a), (b), and (c) represent the best fits following the generalized Debye model for a single relaxation process.

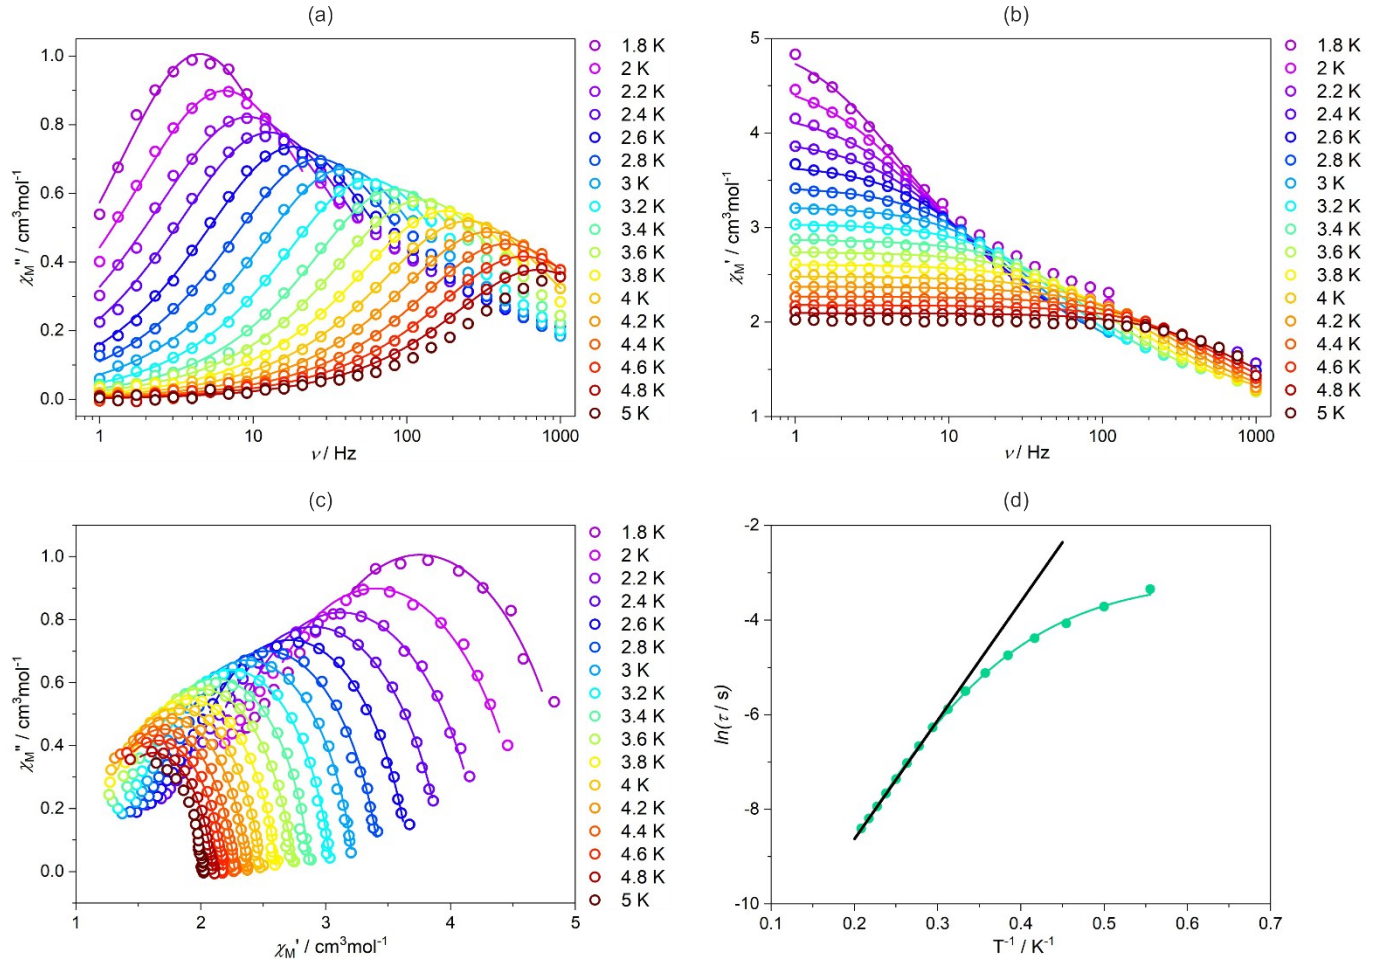

The solid line in (d) shows the best fit taking into account quantum tunnelling of magnetization, and the direct process, in the range of 200–2000 Oe. The  $\tau$  versus  $H_{dc}$  dependence was fitted using the equation (e1):

$$\tau^{-1} = ATH^4 + \frac{a(1 + c^2H^2)}{(1 + bH^2)} \quad (\text{e1})$$

where the first term represented by the  $A$  parameter is related to a field-induced direct process, while the second term represented by three parameters ( $a$ ,  $b$  and  $c$ ) is showing the contribution from quantum tunnelling of magnetization. Following the equation, the best-fit

parameters are:  $A = 1.43(5) \cdot 10^{-12} \text{ s}^{-1} \text{ K}^{-1} \text{ Oe}^{-4}$ ,  $a = 274(28) \text{ s}^{-1}$ ,  $b = 5.3(8) \cdot 10^{-5} \text{ Oe}^{-2}$ , and  $c = 1.7(3) \cdot 10^{-3} \text{ Oe}^{-1}$ .

**Figure S8.** Complete temperature-variable alternate-current (ac) magnetic susceptibility characteristics of **HL3-Dy** under  $H_{ac} = 1 \text{ Oe}$ ,  $H_{dc} = 1000 \text{ Oe}$ , and their analysis: frequency dependences of the out-of-phase susceptibility,  $\chi_M''$  (a), and the in-phase susceptibility,  $\chi_M'$  (b) at various indicated temperatures, together with the related Argand plots (c), and the temperature dependence of the relaxation time,  $\tau$  (d). Coloured solid curves in (a), (b), and (c) represent the best fits using the generalized Debye model for a single relaxation process.

The solid black line in (d) represents the linear fitting following the Arrhenius law ( $\ln \tau = \ln \tau_0 + (U_{eff}/k_B) \cdot T^{-1}$ ) in the range of 3.4–4.8 K extrapolated towards lower temperatures. The solid green line in (d) shows the best fit taking into account Orbach and Raman relaxation processes, together with a field-induced direct process and quantum tunnelling of magnetization (QTM), in the range of 1.8–4.8 K. Therefore, we followed the equation (e2):

$$\tau^{-1} = \tau_0^{-1} \exp\left(\frac{-U_{eff}}{k_B T}\right) + B_{Raman} T^n + \frac{a(1 + c^2 H^2)}{(1 + bH^2)} + ATH^4 \quad (\text{e2})$$

where the first term with two fitting parameters ( $\tau_0$ ,  $U_{\text{eff}}/k_B$ ) represents the Orbach thermal relaxation, the second term indicates the Raman process, the third term shows contribution from the QTM effect, while the last originates from a field-induced direct process. Parameters extracted from the field-dependence of relaxation times at 1.8 K ( $A$ ,  $a$ ,  $b$ ,  $c$ ) were taken as constants to avoid over-parameterization. The best-fit parameters are:  $U_{\text{eff}}/k_B = 31(3)$  K,  $\tau_0 = 1.2(7) \cdot 10^{-6}$  s,  $B_{\text{Raman}} = 0.27(1) \text{ s}^{-1}\text{K}^{-n}$  and  $n = 6.0(3)$ .

### Comment to Figures S7 and S8

For the fitting of the frequency dependences of  $\chi'$  and  $\chi''$  contributions to the  $ac$  magnetic susceptibility, and the related Argand  $\chi''(\chi')$  plots (Figures S7 and S8), the following equations (e3 and e4) of the generalized Debye model for a single relaxation process were used:

$$\chi'(\omega) = \chi_S + (\chi_T - \chi_S) \frac{1 + (\omega\tau)^{1-\alpha} \sin(\pi\alpha/2)}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2(1-\alpha)}} \quad (\text{e3})$$

$$\chi''(\omega) = (\chi_T - \chi_S) \frac{(\omega\tau)^{1-\alpha} \cos(\pi\alpha/2)}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2(1-\alpha)}} \quad (\text{e4})$$

where

$\chi_S$  = the adiabatic susceptibility (at infinitely high frequency of  $ac$  field),  
 $\chi_T$  = the isothermal susceptibility (at infinitely low frequency of  $ac$  field),  
 $\tau$  = the relaxation time,  
 $\alpha$  = the distribution (Cole-Cole) parameter,  
and  $\omega$  is an angular frequency, that is  $\omega = 2\pi\nu$ , with  $\nu$  being for the linear frequency in [Hz] units.

The results of the fittings according to the Debye model for a single relaxation process for **1** are shown in Figures S7 (a–c) and S8 (a–c). The resulting relaxation times ( $\tau$ ) were plotted against applied  $dc$  field at  $T = 1.8$  K (Figure S7 d) and against temperature under the applied  $dc$  field of 1000 Oe (Figure S7 d).
