Calculation

Equation S(1) XRD Williamsone-Hall methods

We could get the information about lattice strain and crystalline size based on Williamson–Hall equation through the full width at half maximum (FWHM) of the XRD peak. The W-H equation is (1),

$$\frac{\beta_{hkl}\cos\theta}{\lambda} = \frac{k\lambda}{D} + 4\epsilon\sin\theta \quad (1)$$

where D is particle size in nanometer, ϵ is the strain component without dimensionless, k is a constant equal to 0.94, λ is wavelength of radiation (1.54056 Å for Cu K α radiation), β_{hkl} is diffraction peak width at half-maximum intensity, and θ is diffraction angle. By plotting $\beta_{hkl}\cos\theta$ versus $4\sin\theta$, we provides more of the crystal structure details, such as the slope and y-intersect of the fitted line represent strain and particle size parameter, respectively.

Equation S(2) To measure electrochemical capacitance, the potential was swept between 0.28 and 0.38 V versus Hg/HgO at ten different scan rates (10, 20, 30, 40, 50, 60, 70, 80, 90 and 100), as shown in Figure S18. The measured capacitive currents are plotted as a function of scan rate and the linear slope is equivalent to twice of the C_{dl} . Ni(Fe)O $_x$ H $_y$ have been determined with an areal capacitance of $\sim 80 \mu\text{F cm}^{-2}$ in the charged state. The specific capacitances for Carbon Clothes, Ni LDH, Fe $_{0.03}$ -Ni LDH, Fe $_{0.03}$ W $_{0.03}$ -Ni LDH and Fe $_{0.03}$ W $_{0.03}$ -Ni LDH^B are determined as 1.8, 1.9, 1.5, 1.7 and 2.9 mF cm $^{-2}$, respectively. ECSA is calculated as follows:

$$A_{ECSA} = \frac{C_{dl}^{sample}}{80\mu\text{F}^{NiO}} \quad (2)$$

Equation S(3) For temperature-dependent measurements, the kinetics of the OER are increased at elevated temperatures from 20°C to 60°C, reflecting the temperature dependence of the chemical rate constant, which is approximately proportional to $\exp(-\Delta H^*/kT)$. The Arrhenius equation is (3),

$$\frac{\partial(\log i_k)}{\partial(1/T)} = \frac{-\Delta H^*}{2.3R} \quad (\eta = 300mV)$$

where ΔH^* is the apparent enthalpy of activation (here after simply termed as the activation energy), i_k is the kinetic current at $\eta = 300$ mV, T is the temperature, and R is the universal gas constant.
