## **Experimental Procedures**

#### 1 Direct growth of Cu<sub>3</sub>P on Cu foam (Cu<sub>3</sub>P/CF) by low temperature plasma

Commercial Cu foam (1 cm×1 cm, 57.4~57.7 mg) is cleaned by ultra-sonication successively in 6 M HCl, water and ethanol, and then dried under vacuum at 60 °C before used. The home-made radio frequency (RF) plasma system shown in our previous report is used for  $Cu_3P/CF$  preparation. Plasma coil is already winded round the tube upstream and next to the furnace. Plasma can be generated at low pressure (1-10 Pa) by radio frequency power input into the coil.

A piece of Cu foam (1 cm×1 cm) is suspended from a small quartz tube and loaded into the center of the furnace. Red phosphorous (0.2 g) in a ceramic boat is placed upstream to the Cu foam with a gap ~ 2 cm where the temperature is same as the Cu foam. Afterwards, the tube is evacuated into 0.1 Pa using a rotary pump and is flushed with high purity Ar (99.999%) three times to remove oxygen and moisture. A mixture of Ar/H<sub>2</sub> flow (Ar 15 sccm and H<sub>2</sub> 5 sccm) is made to flow into the system and the pumping rates is adjusted to keep the tube pressure ~ 18 Pa. The Cu foam is then heated to 200 °C at 10 °C/min. When the desired temperature is reached, plasma is ignited (120 W). A bright reddish violet glow is able to extend to the sample region. The treatment time is 15 min. After treatment, the plasma is turned off and the system is cooled down to room temperature in 15 sccm Ar flow. The mass loading is determined by weighting Cu foam before and after phosphorization using an analytical balance with a nominal precision of 0.01 mg. The P loading is typically 1.2-1.6 mg cm<sup>-2</sup>. The taken-out sample can be directly used to test.

#### 2 Structural characterization

The products are characterized by X-ray diffraction (XRD, Rigaku D/max 200 diffractometer, Cu Kα), scanning electron microscopy (SEM, ZEISS, Merlin Compact), high-resolution transmission electron microscopy (HRTEM, JEM 2100F, 200 kV) and X-ray photoelectron spectroscopy (XPS AXIS-Ultra spectrometer, Kratos Analytical, monochromatic Al Kα radiation). Binding energy of C1s peak from sp2-bonded carbon at 284.5 eV is the reference for correction as general. For TEM observation, the Cu<sub>3</sub>P particles are gathered from the Cu<sub>3</sub>P/CF sample by sonication in ethanol for 30 min. Then a few drops of the suspension are casted onto TEM grids.

#### **3** Electrochemistry measurements

The obtained Cu<sub>3</sub>P/CF sample is directly used as the working electrode for LIBs. Coin type cells are assembled in an argonfilled glove-box, using a lithium foil as counter electrode, 1 M LiPF<sub>6</sub> in ethylene carbonate/dimethyl carbonate = 1/1 in volume with 5 wt% fluoroethylene carbonate (FEC) as the electrolyte and glass fiber (GF/D, Whatman) as the separator. The cells are tested in the voltage range of 0.005 - 2 V (versus Li/Li<sup>+</sup>) at ambient temperature.

#### **4** Numerical calculation

The space size is 0.9 m in the axial direction and 0.03 m in the radial direction. The coil is located from 30 cm to 43 cm away from the entrance, with a total of 14 turns. The final distribution of plasma and magnetic potential can be obtained by decoupling the magnetic potential and thermal transmission equations. Plasma is assumed to be in the local thermal equilibrium (LTE) state. Number density is obtained from the Saha equation.

### Supplementary figures and tables

Fig. S1 Photographs of (a) bare Cu foam, (b) Cu foam after Ar plasma, (c) Cu<sub>3</sub>P/CF.

Fig. S2 SEM images of Cu<sub>3</sub>P/CF and elemental mapping images of P and Cu.

Fig. S3 (a) The CV curves at different sweep rates (from 0.1 to  $1.0 \text{ mV s}^{-1}$ ). (b) The relationship between peak current and scan rate. (c) The normalized capacity contribution ratio of the capacitive- and diffusion-controlled charge versus scan rate.

Fig. S4 (a) Nyquist profiles of the honeycomb  $Cu_3P$  / Cu electrode after 10 and 150 cycles. (b) An equivalent electrical circuit used for fitting the Nyquist profiles. (c) Fitted electrochemical impedance parameters. Generally, the equivalent circuit includes the impedance of pure Ohmic nature (R<sub>s</sub>) corresponding to the overall Ohmic resistance of the cell, an interface impedance corresponding to the SEI layer (including a resistive component R<sub>f</sub> and a capacitive component CPE<sub>1</sub>) and an electrochemical impedance (including a charge-transfer impedance R<sub>ct</sub>, a capacitive component CPE<sub>2</sub> and a Warburg impedance Z<sub>w</sub>), respectively.

Fig. S5 XPS spectra of Cu foam of Cu  $2p_{3/2}$  and P 2p after Ar plasma treatment.
