Methods

Chemicals. Rhodium(III) acetylacetonate (Rh(acac)₃, 97%) and oleylamine (OAm, 70%) were obtained from Sigma-Aldrich. Triruthenium dodecacarbonyl (Ru₃(CO)₁₂, 99%) was obtained from Acros. L-ascorbic acid (reagent grade, 99%) was purchased from J&K Scientifc. Ethanol and cyclohexane were supplied by Beijing Tongguang Fine Chemicals Company. Perchloric acid (GR, 70%-72%) was purchased from Sinopharm Chemical Reagent Co. Ltd (SCRC). KOH (95%) was obtained from Aladdin. Nafion (5 wt%) was obtained from Alfa Aesar. All the chemicals were used as received without further purifcation, and all solutions were freshly prepared with water (18 MΩ/cm) by passing through an ultra-pure purification system.

Synthesis of RuRh nanosheets. The ultrathin RuRh nanosheets were synthesized as we reported.^[1] ypically, 10 mg Rh(acac)₃, 48 mg Ru₃(CO)₁₂, 40 mg L-ascorbic acid and 5 mL oleylamine were added into 15 mL glass pressure vial (Synthware, P160001D) successively. Afterwards, the capped vial was placed in an oil bath and stirred at 45 °C for 60 min, and then heated to 180 °C in 20 min and kept at this temperature for 120 min before cooling down to room temperature. Then, the RhRu nanosheets were collected by centrifugation and washed three times with an ethanol/cyclohexane mixture. Then, the as-synthesized RuRh NSs was loaded onto Ketjen-300J carbon with a metal loading amount of ~20%.

Preparation of RuRh@(RuRh)O₂ core@shell nanosheets. The RuRh NSs/C was annealed in air at 286 °C for 2 h to obtain the RuRh@(RuRh)O₂ core@shell nanosheets, denoted as RuRh@(RuRh)O₂ NSs/C.

Material characterization. TEM images were obtained from a transmission electron microscope (TEM, Hitachi, HT7700) at 100 kV. The high-angle annular dark-field scanning transmission electron microscopy (HAAD-STEM) images and STEM energy-dispersive X-ray spectroscopy (STEM-EDS) elemental mapping analysis were performed on an JEOL ARM 300F transmission electron microscope at an accelerating voltage

of 300 kV. Powder X-ray diffraction (XRD) patterns were collected on a Bruker D2 Phaser X-Ray Diffractometer with Cu K α radiation ($\lambda = 1.5406$ Å) at a voltage of 40 kV and a current of 40 mA. XPS data were obtained from Thermo Scientifc Escalab 250Xi using a monochromated Al- $K\alpha$ (1486.5 eV) X-ray radiation and all the binding energies were calibrated to C 1s (284.8 eV).

Catalyst Preparation. The RuRh NSs/C and RuRh@(RuRh)O₂ NSs/C were redispersed in a solvent mixture containing deionized water, isopropanol and Nafion (D-521) (V/V/V=1/1/0.05) to form a catalyst homogeneous ink (1 mg mL⁻¹) by sonification.

Electrocatalytic Measurements. Electrochemical measurements were conducted with a CHI 760e (CH Instruments, Inc., Shanghai) in a standard three-electrode system, consisting of a glassy carbon (GC) working electrode (Pine Instruments, 0.196 cm^{-2}), saturated Ag/AgCl electrode and graphite rod used as the working, reference and counter electrodes, respectively. For each measurement, $20 \ \mu\text{L}$ of the catalyst ink was deposited on the GC working electrode (5 mm, 0.196 cm^2) with the catalyst metal mass loading of 20.4 ug_{metal} cm⁻². Linear sweep voltammetries were performed in a O₂-saturated 0.1 M HClO₄ and 1 M KOH electrolyte with a potential range between 1.2 and 1.6 V *versus* RHE at a scan rate of 10 mV s⁻¹ with iR compensations and the rotating speed fixed at 1,600 rpm. All the potentials were calibrated to the reversible hydrogen electrode (RHE). For the long-term stability test, 100 uL of the catalyst ink was dropped onto FTO conducting glass (area: 1×1 cm²) with the metal mass loading of 20 ug_{metal} cm⁻². Stability was measured by chronopotentiometry at constant current of 5 mA cm⁻².

Rotating ring disk electrod (RRDE) measurements were performed in the collection mode in a O_2 -saturated 0.1 M HClO₄ electrolyte, wherein recording the OER was conducted on the disk electrode, the ring electrode was potentiostated at 0.9 V at which solution phase Ru⁴⁺ (dissolution product in acid solution) was deposited onto the ruthenized-Pt ring electrode at a diffusion control rate. The disk catalyst metal mass loading was 20.4 ug_{metal} cm⁻², with a sweep rate 10 mV s⁻¹ and a rotation rate of 1600 rpm.

Calculation Setup. All the calculations are performed by the density functional theory (DFT) within the CASTEP codes ^[2]. We have applied the generalized gradient approximation (GGA) in the parametrization of Perdew-Burke-Ernzerhof (PBE) for the exchange-correlation energy ^[3-5]. The ultrasoft pseudopotential scheme with the 380 eV cutoff energy has been chosen^[6] with the algorithm Broyden-Fletcher-Goldfarb-Shannon (BFGS) for all related ground state geometry optimization^[7]. The core RuRh is constructed with six-layered thickness. Meanwhile, the shell oxidation layer is modelled based on the two-layered of RuO2 (112) surface. Along the z-axis, we applied 15 Å vacuum space for all the models. Considering the DFT computational cost, the Monkhost-Pack reciprocal space integration was performed using coarse k-points with a mesh of $2 \times 2 \times 1$ ^[8], which was guided by the initial convergence test. Thus, the overall total energy for each step is converged to less than 5.0x10-5 eV per atom. The Hellmann-Feynman forces on the atom were converged to less than 0.001 eV/Å.

Data availability. The data that support the plots within this paper and other finding of this study are available from the corresponding author upon reasonable request.
