## **Experimental section**

### **Materials and chemicals**

Ammonium Paratungstate  $[(\text{NH}_4)_{10}\text{H}_2\text{W}_{12}\text{O}_{42} \cdot x\text{H}_2\text{O}]$  and Cobalt nitrate hexahydrate  $[\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}]$  were purchased from Aladdin Chemical Reagent Co., Ltd. Ni foams were purchased from Shanghai Tanqi new material technology business department. Ethanol was obtained from Tianjin Kermel Chemical Reagent Co., Ltd. All chemicals were used without any further purification. Deionized water was used throughout the experiments.

### **Synthesis of porous cobalt tungsten oxynitride polyhedron on Ni foam**

Firstly, Ni foam (NF) was cleaned by 2 M  $\text{HNO}_3$  aqueous solution and deionized water with ultrasonication for 15 min in each step to remove the surface oxide layer. Secondly, one piece of treated NF (3×5 cm) was vertically placed into a 100 mL teflon autoclave with 80 mL homogenous solution containing 0.125 mmol  $(\text{NH}_4)_{10}\text{H}_2\text{W}_{12}\text{O}_{42} \cdot x\text{H}_2\text{O}$  and 1.5 mmol  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ . Subsequently, the teflon-lined stainless autoclave was sealed tightly and heated at 180°C for 10 h. After it naturally cooled to room temperature, the Ni foam coated with  $\text{Co}_4\text{W}_6\text{O}_{21}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$  precursor (named as CoWO precursor) was taken out. After sonication for 5 min, the CoWO/NF precursor was washed with water and ethanol successively several times and then dried at 60°C for 12 h. To obtain cobalt/tungsten nitride polyhedron, the as-prepared CoWO/NF precursor was treated with controlled nitridation at 600°C for 2 h with a heating rate of 5°C min<sup>-1</sup> in  $\text{NH}_3$  atmosphere, followed by naturally cooling to room temperature. The product was denoted as Co/WN-600. To tune the microstructures and composition of the cobalt/tungsten nitride polyhedron, the nitridation was also carried out at 550°C (Co/WN-550) and 650°C (Co/WN-650), while keeping other parameters unchanged.

### **Characterizations**

The morphology and phase composition of as-prepared materials were studied by

scanning electron microscope (SEM, Hitachi S-4800 at an accelerating voltage of 5 kV), transmission electron microscopy (TEM, JEM-2100 at an accelerating voltage of 200 kV) and Powder X-ray diffraction instrument (Bruker D8 diffractometer using Cu K $\alpha$  ( $\lambda=1.5406$  Å) radiation with accelerating voltage 40 kV). The chemical state of the materials was characterized by X-ray photoelectron spectroscopy (XPS), performed on VG ESCALAB MK II using an Mg Ka (1253.6 eV) achromatic X-ray radiation.

### **Electrochemical measurements**

All electrochemical measurements were carried out on a CHI 760E electrochemical workstation in 1 M KOH electrolyte. The electrochemical performance and characterization of as-prepared materials were tested in a three-electrode system. The as-prepared materials (Co/WN anchored on NF (1 $\times$ 1.5 cm)) were directly used as working electrode. Graphite rod and Hg/HgO electrode were used as the counter electrode and reference electrode, respectively. Before the electrochemical measurements, the electrolyte solutions (1 M KOH solution) were bubbled with N<sub>2</sub> for 1 hour to remove the dissolved gases. The activity of the electrocatalysts were evaluated by linear sweep voltammograms (LSV) tests and the polarization curves were obtained at a scan rate of 2 mV s<sup>-1</sup>, which were performed after 20 cycles of cyclic voltammetry (CV) tests. In all measurements, the final potentials were calibrated to reversible hydrogen electrode (RHE) based on the Nernst equation:  $E_{(RHE)} = E_{(Hg/HgO)} + 0.059 \times pH + 0.098$  V. The electrochemical double layer capacitance ( $C_{dl}$ ) were obtained through cyclic voltammetry (CV) tests carried out at different scan rates in the non-faradaic potential range. The durability test was evaluated by chronoamperometry measurements at a static overpotential, during which the current variation with time was recorded. The overall water splitting measurement was carried out in a standard two-electrode system by using self-supported Co/WN polyhedron electrode as both cathode and anode in alkaline medium.

Figure S1 The photograph of different reaction systems. (1) Ammonium tungstate  $[(\text{NH}_4)_{10}\text{W}_{12}\text{O}_{41} \cdot x\text{H}_2\text{O}]$  as W source; (2) Ammonium paratungstate  $[(\text{NH}_4)_{10}\text{H}_2\text{W}_{12}\text{O}_{42} \cdot x\text{H}_2\text{O}]$  as W source; (3) Sodium tungstate ( $\text{Na}_2\text{WO}_4$ ) as W source.

As shown in Figure S1, Ammonium tungstate (or sodium tungstate) and cobalt nitrate react at room temperature. When the two solutions of Ammonium tungstate (or sodium tungstate) and cobalt nitrate are mixed, precipitation will occur instantly, so it is difficult to obtain a well-defined structured materials. However, when ammonium paratungstate is selected as the tungsten source, a clear and transparent solution is obtained, suggesting that ammonium paratungstate can only react with cobalt nitrate under certain conditions. This result proves that the choice of tungsten source is crucial for the synthesis of CoWO precursors with a well-defined structure.

Figure S2 XRD pattern of CoWO precursors.

Figure S2 shows the XRD pattern of the sample obtained after hydrothermal reaction. As shown in Figure S2, the sample has very good crystallinity. It can be observed that except for the diffraction peaks of nickel foam, the other diffraction peaks belong to  $\text{Co}_4\text{W}_6\text{O}_{21}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$  (PDF# 47-0142), suggesting that ammonium paratungstate reacts with cobalt nitrate to form a stable cobalt tungsten oxide hydroxide hydrate during the hydrothermal reaction. For convenience, the  $\text{Co}_4\text{W}_6\text{O}_{21}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$  precursor was named CoWO precursor.

Figure S3 The high-magnification SEM images of CoWO precursor (a) and Co/WN-600 sample (b).

As displayed in Figure S3, the CoWO precursor polyhedron has a smooth surface. After controllable nitridation, the polyhedron morphology is well maintained but the volume shrinks slightly and the surface becomes rough. Importantly, it is obviously seen that there are many pores and nanoparticles generated on the surface, which may offer efficient pathway for electrolyte diffusion and expose more catalytic active sites.

Figure S4 XRD pattern of powder catalysts.

In order to better observe the crystal structure of the Co/WN catalysts, the remaining powder samples after the hydrothermal reaction are collected and were undergone the same heat treatment as self-supporting samples. Figure S4 shows the XRD pattern of the powder catalysts. As observed in Figure S4, in addition to the diffraction peaks of  $W_5N_4$ , other diffraction peaks located at  $44.2^\circ$ ,  $51.5^\circ$  and  $75.8^\circ$  can be attributed to the (111), (200) and (220) planes of Co (PDF# 15-0806), indicating the cobalt species are reduced to metallic cobalt in an ammonia atmosphere.

Figure S5 XRD patterns of Co/WN-550 and Co/WN-650 samples.

As shown in Figure S5, for Co/WN-550, in addition to the diffraction peaks of nickel foam and  $W_5N_4$ , other diffraction peaks can be attributed to  $CoWO_4$  (PDF# 72-0479), indicating that the CoWO precursors can't be completely convert to Co/WN at a relatively low nitridation temperature. As the nitridation temperature rises to 650°C, the diffraction peak is similar to that of Co/WN-600 except that the intensity of diffraction peak becomes stronger. This result reveals that the crystallinity and the content of Co/WN can be adjusted by regulating the nitriding temperature.

Figure S6 SEM images of Co/WN-550.

As shown in Figure S6, the morphology of Co/WN-550 is similar to the CoWO precursor, but the surface of polyhedron is very different. A large number of holes are formed due to the volume shrinkage during the high temperature nitriding process.

Figure S7 SEM images of Co/WN-650.

As shown in Figure S7, when rising the calcination temperature to 650°C, the polyhedron structure is still well maintained. However, the surface of the polyhedron becomes rougher and it can be obviously seen that lots of nanoparticles are loaded on the surface of the Co/WN-650, implying that the nitriding temperature is too high.

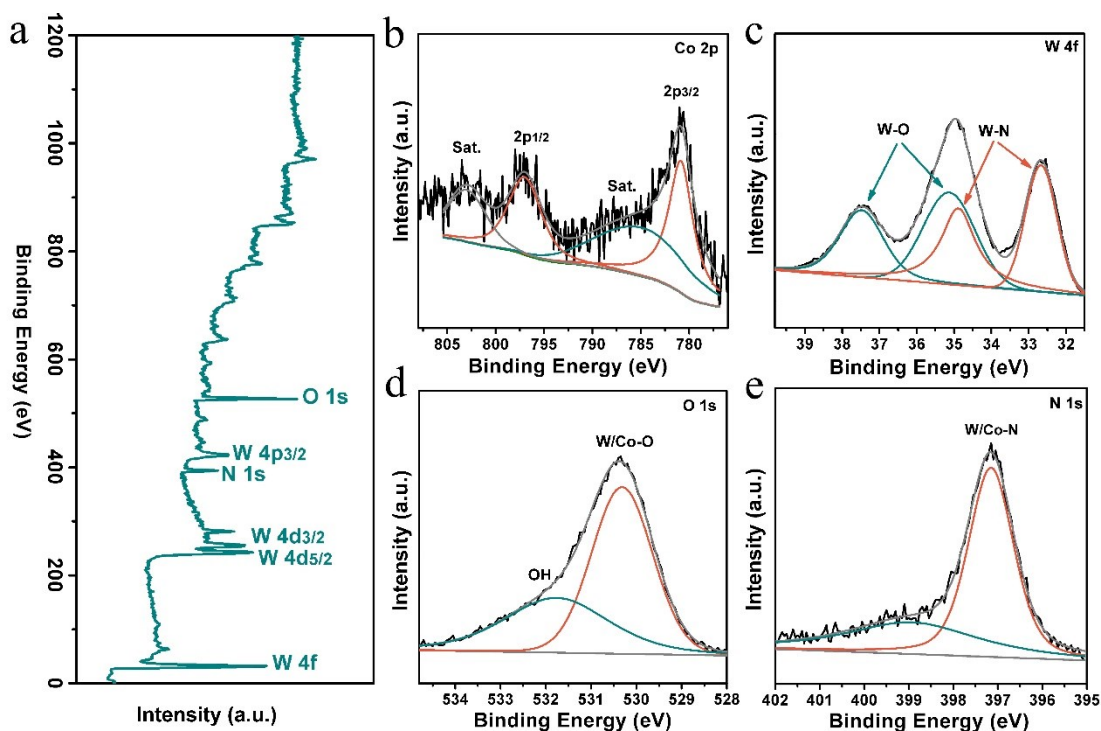

Figure S8 XPS spectra of Co/WN-550: (a) wide scan spectrum and the high-resolution spectra of (b) Co 2p, (c) W 4f, (d) O 1s and (e) N 1s.

The XPS survey spectrum of the Co/WN-550 clearly indicate the presence of W, Co, O and N elements. From the high-resolution spectra (Figure 8b-8e), it can be seen that the Co 2p spectrum is similar to that of CoWO precursor, while the XPS spectra of W 4f, O 1s and N 1s are different from that of CoWO precursor. The results indicate that the main phase of Co/WN-550 sample is  $\text{CoWO}_4$ . The high resolution spectrum of W 4f and N 1s prove the existence of Metal-N bonds, indicating a small amount of metal-N species were generated on the surface.

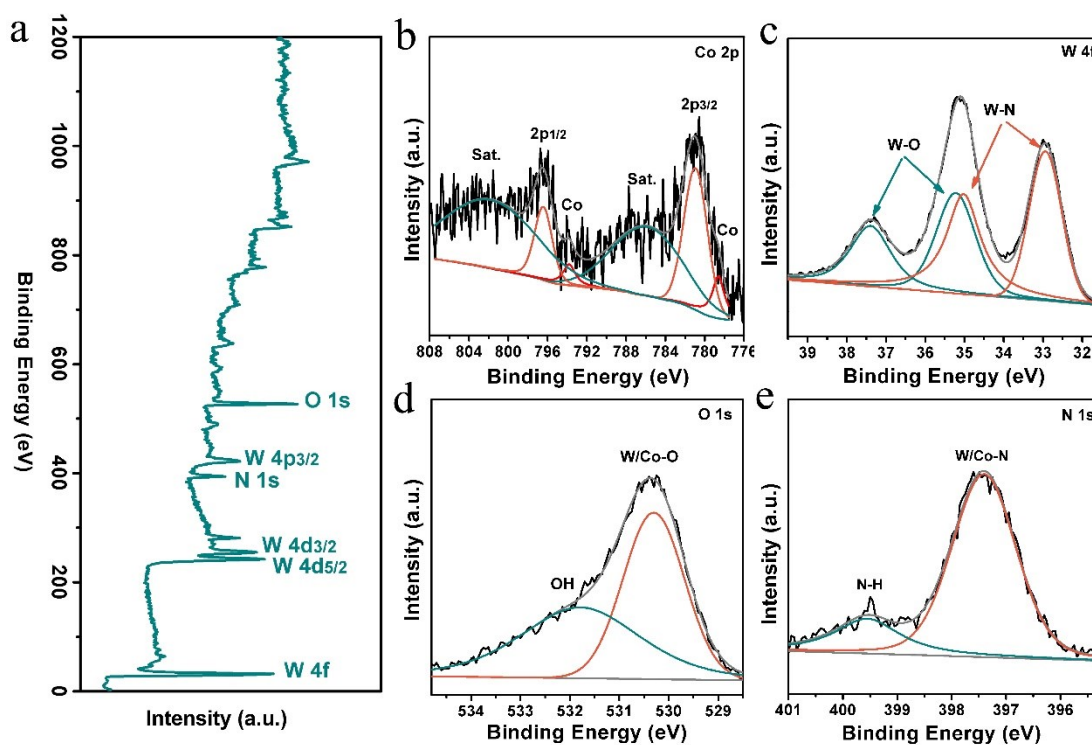

Figure S9 XPS spectra of Co/WN-650: (a) wide scan spectrum and the high-resolution spectra of (b) Co 2p, (c) W 4f, (d) O 1s and (e) N 1s.

Figure S9 shows the XPS spectra of Co/WN-650 sample. The high resolution spectra of W 4f can be divided into two pairs of distinct peaks, belonging to W-N and W-O. The XPS spectra of O 1s and N 1s are also similar to those of Co/WN-600 sample, suggesting the chemical composition of Co/WN-650 sample is similar to Co/WN-600, which is consistent with the XRD results.

Figure S10 Calculation of exchange current density of CoWO, Co/WN-550, Co/WN-600 and Co/WN-650 in 1 M KOH.

The exchange current density ( $j_0$ ) was calculated using extrapolation method. Based on Tafel equations,  $j_0$  for Co/WN-600 sample is  $6.92 \text{ mA cm}^{-2}$ , which is higher than that of CoWO ( $0.84 \text{ mA cm}^{-2}$ ), Co/WN-550 ( $4.17 \text{ mA cm}^{-2}$ ) and Co/WN-650 ( $5.13 \text{ mA cm}^{-2}$ ).

The capacitive currents were measured in a potential range where no faradic processes were observed. A potential of 0.1-0.2 V at scan rates of 30-100 mV s<sup>-1</sup> was utilized. The differences in the current-density variation ( $\Delta j = j_a - j_c$ ) at the potential of 0.15 V plotted against the scan rate were fitted to estimate the electrochemical double-layer capacitances ( $C_{dl}$ ), which was proportional to the ECSA.

Figure S11 CV curves for CoWO, Co/WN-550, Co/WN-600 and Co/WN-650 in 1 M KOH with different rates from 30 to 100 mVs<sup>-1</sup> in the region of 0.1-0.2 V.

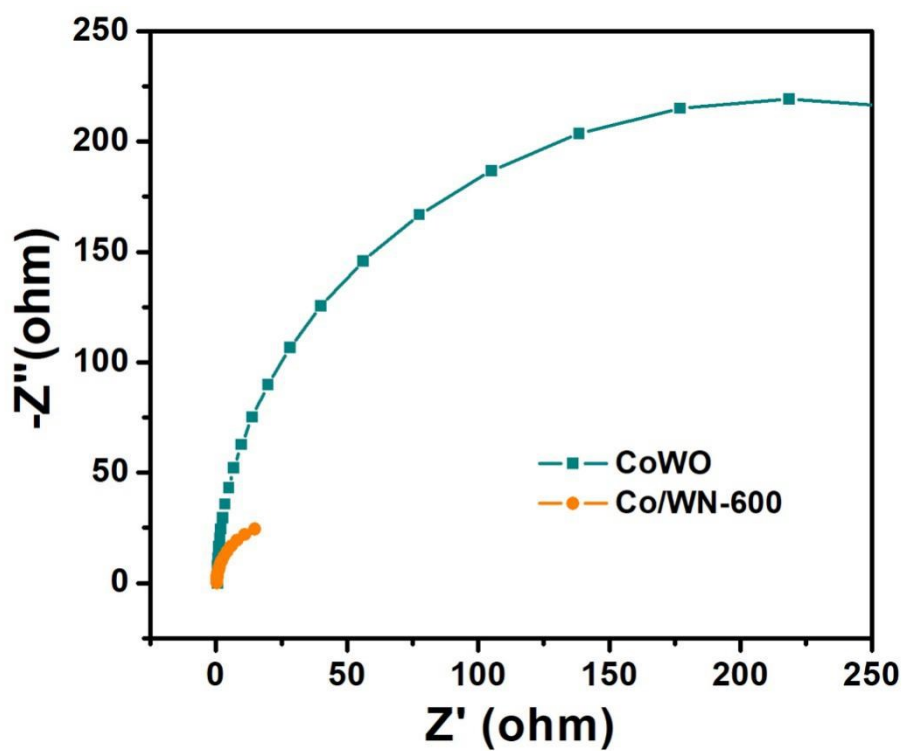

Figure S12 Nyquist plots for CoWO and Co/WN-600 at open circuit voltage in the frequency range of  $10^5$ -0.01 Hz.

As observed from the Nyquist plots (Figure S12), the Co/WN-600 catalyst has a smaller charge transfer resistance, indicating a faster electron transfer.

Figure S13 CV curves for CoWO, Co/WN-550, Co/WN-600 and Co/WN-650 in 1 M KOH with different rates from 20 to 60  $\text{mV s}^{-1}$  in the region of 1.15-1.25 V.

Figure S14 Solar power assisted water splitting device (driven by a solar panel with a voltage of 1.55 V).
