1. Materials and Methods

All acids were commercially available. WP5 was synthesized according to previously reported procedures.\cite{S1,S2} Supramolecular polymers were prepared according to the previous literatures.\cite{S3,S4} \textsuperscript{1}H NMR spectra were collected on a Bruker-AV400. Two-dimensional NOESY experiments were collected on a Bruker-AV400. Fourier-transform IR (FT-IR) spectra were recorded on SHIMADZU QATR-S. Scanning electron microscopy (SEM) images were performed on a JEOL JSM-7610F. Powder X-Ray Diffraction (PXRD) data was collected on a Bruker D8 ADVANCE. Differential Scanning Calorimeter (DSC) measurements were carried out using TAQ100 from -60 to 100 °C with a heating rate of 10 °C min\textsuperscript{-1} under nitrogen atmosphere. Thermogravimetric analysis (TGA) was carried out using a TGA5500, the heating rate was 10 °C min\textsuperscript{-1} from 30 to 600 °C in nitrogen atmosphere. Rheology measurements were performed on an Anton Paar MCR 92. The adhesion strength measurements were performed on a HY-0580 Electronic tensile testing machine. The conductivity of solution was collected on a DDSJ-308F. The bulk resistivity was carried out using a ST2643. Powder resistivity was collected on a ST2722 resistivity of the powder tester.

Experimental Section

Preparation of adhesion layers: pillar[5]arene-based supramolecular adhesives were coated on the surface of a plate (glass, steel, PMMA, PTFE), then a new plate was covered on the adhesive layer. After pressing and heating for 30 min, a thin coating layer was formed and two surfaces were adhered firmly.

Temperature- or RH-dependent adhesion tests: The adhered plates were stored at different temperatures or relative humidity for three hours before lap-shear tests.

2. Supramolecular Adhesives Preparation and Characterization

All pillar[5]arene-based supramolecular adhesives were synthesized according to present literatures.\cite{S1,S2} By simply heating the aqueous solution WP5 and acids with different molar ratios at 70 °C, pillar[5]arene-based bulk supramolecular polymer materials were obtained. For example, water-soluble pillar[5]arene WP5 (2.6 g, 1.1 mmol) and DL-tartaric acid (1.7g, 11 mmol) were added into a 100 mL beaker, and then 15 mL of water was added. PD-2 was obtained after heating the mixture solution for 12 h at 70 °C. With the evaporation of water, the aqueous solution was converted to transparent and highly viscous bulk supramolecular adhesives.

Table S1. Pillar[5]arene-based supramolecular adhesives.

15. DFT Calculation

All-electron DFT calculations have been carried out by the latest version of ORCA quantum chemistry software (Version 5.0.1). The BLYP functional was adopted for all calculations. For geometry optimization calculations, the def2SVP basis set was used. The DFT-D3 with BJ-damping was applied to correct the weak interaction to improve the calculation accuracy. Then, the interaction energy between adhesive and basis materials were calculated.\cite{S5,S6}

**Molecular Dynamic Simulation**

The interaction energy of the interface between pillar[5]arene-based supramolecular adhesive PT-2 and hydrophilic substrates (glass and steel) was calculated by molecular dynamics to verify the adhesion mechanism of PT-2 on hydrophilic substrates. According to our previous calculation method,[97] we used Materials Studio software to carry out corresponding modeling and interface energy calculation. However, the molecular model was slightly different compared to before. The contact cell between PT-2 and substrate surface with periodic structure was expanded to 43.4 × 43.4 Å$^2$. The thickness of glass was about 25.7 Å. The thickness of Steel was about 8.5 Å. Steel substrate contains 6 layers of Fe atoms. To equilibrate the model, a equilibrate process was followed under constant temperature and constant volume (NVT ensemble) at 298 K for 2000 ps. Then, the interaction energy between adhesive and basis materials were calculated by the following formula.

$$E_{\text{interfacial}} = E_{\text{total}} - (E_{\text{adhesive}} + E_{\text{substrate}})$$

$E_{\text{interfacial}}$: Interaction energy between supramolecular adhesive materials and substrate, and minus means adsorption.

$E_{\text{total}}$: The total potential energy of adhesive-substrate system.

$E_{\text{adhesive}}$: The potential energy of adhesive.

$E_{\text{substrate}}$: The potential energy of substrate.

**Table S4.** Interaction energy between PT-2 and hydrophilic substrates.
