Synthesis. Rod-like pink crystals of $\left[\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{NO}\right] \mathrm{MnCl}_{3}$ (compound 1) were obtained from the evaporation of concentrated HCl solution $(36 \%, \mathrm{w} / \mathrm{w})$ containing stoichiometric amounts of $\mathrm{N}, \mathrm{N}-$ dimethylethanolamine and $\mathrm{MnCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ after several weeks. The phase purity of compound 1 was validated by IR and powder X-ray diffraction (PXRD) measurements (Figs. S1 and S2).

Single crystal X-ray diffraction. Suitable crystals were selected for structural determination. X-ray diffraction data were collected at 223,293 and 393 K with Mo K $\alpha$ radiation ( $\lambda=0.71073$ Å) through a Rigaku Saturn 924 CCD diffractometer. The crystal structures at various temperatures were solved by direct methods and refined by the full-matrix methods based on $F^{2}$, employing SHELXTL2014 software package. And the crystallographic data of compound 1 at 223 K was executed with a twin data reduction and refinement. Non-H atoms were refined anisotropically and H atoms were positioned geometrically. The relationship of the cells in the three crystal structures is $a$ (223 $\mathrm{K}) \approx b(293 \mathrm{~K}) \approx c(393 \mathrm{~K}), b(223 \mathrm{~K}) \approx c(293 \mathrm{~K}) \approx a(393 \mathrm{~K})$, and $c(223 \mathrm{~K}) \approx a(293 \mathrm{~K}) \approx b(393 \mathrm{~K})$.

Powder X-ray diffraction (PXRD) measurements. Rigaku Smartlab Powder X-Ray Diffractometer was used to check the phase purity of desired compound. The experimental PXRD patterns were recorded in the $2 \vartheta$ range of $5^{\circ}-45^{\circ}$ with a step size of $5^{\circ} / \mathrm{min}$. The experimental PXRD patterns obtained at 223, 293 and 393 K match well with the calculated data based on the corresponding single-crystal structures (Fig. S2), which solidly confirm the purity of the as-grown crystals and the structural phase transitions of compound 1.

Differential scanning calorimetry (DSC) and dielectric measurements. DSC measurements of compound 1 were performed on the polycrystalline samples that were placed in aluminum crucibles using a NETZSCH DSC 200 F3 instrument within the temperature range of 220-300 K and 350-400 K under a nitrogen atmosphere with a heating/cooling rate of $10 \mathrm{~K} \mathrm{~min}^{-1}$. The exploration of dielectric properties was carried out on a Tonghui TH2828A apparatus upon pressed-powder pellets which were deposited as the electrodes.
experiments were carried out on the polycrystalline samples of compound $\mathbf{1}$ at a sweeping rate of $10 \mathrm{~K} \mathrm{~min}^{-1}$, using an unexpanded laser beam with low divergence (pumped by an Nd:YAG laser with $1064 \mathrm{~nm}, 5$ ns pulse duration, 10 Hz repetition rate) as fundamental beam. The instrument model is Ins 1210058, INSTEC Instruments. And the laser was Vibrant 355 II instrument from OPOTEK. The numerical values of the nonlinear optical coefficient for SHG have been determined by comparing with $\mathrm{KH}_{2} \mathrm{PO}_{4}$ (KDP) as the reference standard.

Ultraviolet-visible (UV-vis) absorption and fluorescence spectrometry. UV-Vis measurement of compound 1 was documented in a Shimadzu UV-2600 spectrophotometer with an ISR-2600Plus integrating sphere functioning from 200 to 900 nm , using $\mathrm{BaSO}_{4}$ as the $100 \%$ reflectance reference. The emission and excitation spectra were collected on an Edinburgh FLS-920 fluorescence spectrometer based on the solid states.

Fig. S1 IR spectrum of compound 1 at 293 K.

Fig. S2 The measured PXRD patterns of compound 1 match well with the simulated ones based on the corresponding crystals structure at 223, 293 and 393 K .
