Experimental Methods

Preparation of pristine Co_3O_4

In a typical synthesis process, 2.19 g of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, 1.40 g of methenamine and 0.10 g of sodium laurylsulfonate were mixed with 200 mL ethylene glycol under vigorous magnetic stirring and reacted in a Teflon-lined stainless-steel autoclave for 24 h at 180 °C. The pink precipitation was obtained after rinsing several times with ethanol and purified water. The final product was collected by annealing at 500 °C for 2 h in air and denoted as pristine Co_3O_4 .

Synthesis of $\text{Co}(\text{OH})_2$ nanoplates

g- Co_3O_4 nanocomposite was synthesized via a facile hydrothermal reaction. 0.1 g of pristine Co_3O_4 and 0.15 g of NaNO_3 were added to 25 mL of home-made graphene oxide solution (1 mg/ml) and sonicated for 10 min. Then, 3 mL of NH_3 aqueous solution and 0.3 mL of hydrazine hydrate were added. Finally, the solution was transferred into a Teflon-lined stainless-steel autoclave and heated at 180 °C for 3, 6, 9, 12 h respectively, denoted as g- Co_3O_4 3h, g- Co_3O_4 6h, g- Co_3O_4 9h, g- Co_3O_4 12h. While cooling to room temperature, the solid products were filtered and rinsed several times with ethanol and distilled water and dried for 12 h.

Materials Characterization:

Scanning electron microscopy (SEM) images were taken on a Hitachi S4800 scanning electron microscopy. Nitrogen adsorption-desorption measurements were conducted using a Quantachrome NOVA4200e analyzer. X-Ray diffraction (XRD) measurements were conducted on a SmartLab diffractometer using Cu K α radiation ($\lambda = 0.15406$ nm) at a scanning rate of 0.02 deg./ sec. X-Ray photoelectron spectroscopy (XPS) analysis was recorded on a thermo scientific NEXSA system, using monochromatic Al K α radiation (1486.6 eV) operating at 25 W.

Electrochemical Measurement:

The electrochemical tests towards OER performance were conducted on an electrochemical workstation (CHI 760E) with a standard three-electrode cell at room temperature. The as-prepared samples as the working electrode, a Pt wire as the counter electrode, and a standard Ag/AgCl electrode with an additional salt bridge as the reference electrode were used in testing under 1 M KOH. All potentials were calibrated versus RHE, through the equation: $E(\text{RHE}) = E(\text{Ag/AgCl}) + 0.197 + 0.059 \times \text{pH}$ (the unit is volt). Linear sweeping voltammetry (LSV) was carried out at a scan rate of 5 mV s^{-1} , and 95% iR compensation. Tafel slopes were derived from corresponding OER polarization curves and fitted to the Tafel equation $\eta = b \log j + a$, where η is overpotential, j the current density, and b the Tafel slope. Electrochemical impedance spectroscopy (EIS) was performed over a frequency range from 100 kHz to 0.01 Hz with the potential of 1.6 V vs RHE. Electrochemical surface area (ECSA) was measured by cyclic voltammetry (CV) from 0.2V~0.3V.
