Computational Details

Crystal structure data were downloaded free of charge as a CIF from The Cambridge Crystallographic Data Centre (CCDC) website (<https://www.ccdc.cam.ac.uk/>). Structures were simplified for calculations by deleting the lowest-occupancy atom(s) in each disordered pair/triplet in Olex2 to eliminate positional disorder.¹ The resulting structures were subsequently written as a CIF with Olex2 for use as input.

Gas-phase geometry-optimisation and single-point energy (SPE) calculations were performed using the Cambridge Serial Total Energy Package (CASTEP) in the BIOVIA Materials Studio 2019 suite.² For calculations, all target and solvent molecules were included and assumed to be at full occupancy. Calculations were performed using DFT-D2 as implemented by Grimme³ with a PBE GGA functional.⁴ A plane-wave basis set with tabulated ultrasoft pseudopotentials,^{5,6} and a Pulay density-mixing scheme were employed for all calculations.⁷ Geometry optimisations utilized a variant of the BFGS quasi-Newton minimiser.⁸ Prior to execution of geometry optimisation calculations, unit cells were reduced to primitive unit cells where symmetry was reduced to triclinic *P*1. Geometry optimisations were performed in two rounds, with the first using CASTEP “express” settings followed by a round using tighter convergence criteria. Unit cell parameters were not optimized, and no other geometric constraints were applied for any geometry optimization calculations. Round one of the geometry optimisation was performed with a plane-wave basis set energy cut-off of 300 eV using a standard FFT grid (grid size: 1.5, maximum g-vector size: 13.3104 1/Å) and utilising the following convergence tolerances: energy of 0.001 eV/cell, maximum force of 100.0 eV/Å, maximum stress of 100.0 GPa, and maximum displacement of 100.0 Å for a maximum of 200 iterations. Electronically, the first round of calculations were run with a medium energy cutoff, an SCF tolerance of 1.0×10^{-4} eV/cell over a maximum of 100 SCF cycles with a convergence window of 2 and a coarse k-point set (1 x 1 x 1). Typically, first round jobs could be completed via running parallel on 40 cores. Round two of the geometry optimisation was performed with a plane-wave basis set energy cut-off of 340 eV using a standard FFT grid (grid size: 1.5, maximum g-vector size: 14.1700 1/Å) and utilising the following convergence tolerances: energy of 1.0×10^{-5} eV/atom, maximum force of 0.05 eV/Å, maximum stress of 0.1 GPa, and maximum displacement of 0.002 Å for a maximum of 200 iterations. Electronically, the second round of calculations was run with a fine energy cutoff, an SCF tolerance of 1.0×10^{-6} eV/atom over a maximum of 100 SCF cycles with a convergence window of 3 and a medium k-point set (1 x 1 x 1). Typically, second round jobs could be completed via running parallel on 55–100 cores. The final geometry optimised structure was utilized for SPE calculations, which were performed using the same criteria as in the second round of geometry optimisations. In order to obtain the SPE for the guest alone, the framework and all ancillary guests were deleted, leaving only the guest of interest. The SPE calculation was then performed on this new structure file containing only the guest of interest. The inverse was then completed to obtain the SPE for the host and ancillary guests (i.e., the guest of interest was deleted) and the SPE calculation was performed on the new structure file without the guest.

For asymmetric unit comparison (computed versus experiment), the geometry optimised structure file (.xsd) was exported as a CIF through Materials Studio. The geometry optimised structure was then compared to the experimental structure (without hydrogens and disordered atoms) and RMSD values were generated via a Structure Overlay calculation performed in Mercury.⁹

Averaged non-H *B*-factors for each guest were calculated by averaging the U_{eq} values obtained from the respective CIFs. All standard uncertainties were also appropriately averaged by summing the squares of all individual standard uncertainties followed by taking the square root of the resulting value and subsequently dividing by the quantity of values averaged. The averaged U_{eq} values with standard uncertainties were then scaled to averaged *B*-factor values by multiplying by $8\pi^2$.

Hirshfeld surfaces for Figures 2 and 3 were constructed using *CrystalExplorer* 17.5 (revision: f4e298a, build: 2017-05-01 03:35).^{10,11} Default settings within the program were used to generate and visualize the Hirshfeld surfaces in high resolution.

All calculations were performed using computing resources maintained by Pfizer's High Performance Computing facility. CASTEP jobs were specifically executed on the Delta cluster. Delta's computational resources are scheduled and managed with Slurm. Application environments are accessed with Lmod. Remote access is provided with SSH and NICE when GPU accelerated graphical environments are required. All nodes run Red Hat Enterprise Linux 7. CPU nodes feature 2 x Intel® Xeon® Gold 6148 CPUs @ 2.40GHz and 192 GB of memory. GPU nodes feature 2 x Intel® Xeon® Gold 6140 CPUs @ 2.30GHz, 4 x Nvidia V100, and 384 GB memory. All nodes are connected by non-blocking EDR Infiniband.

Additional Figures

Figure S1. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of (+)-artemisinin@**1a**. Hydrogen atoms have been omitted.

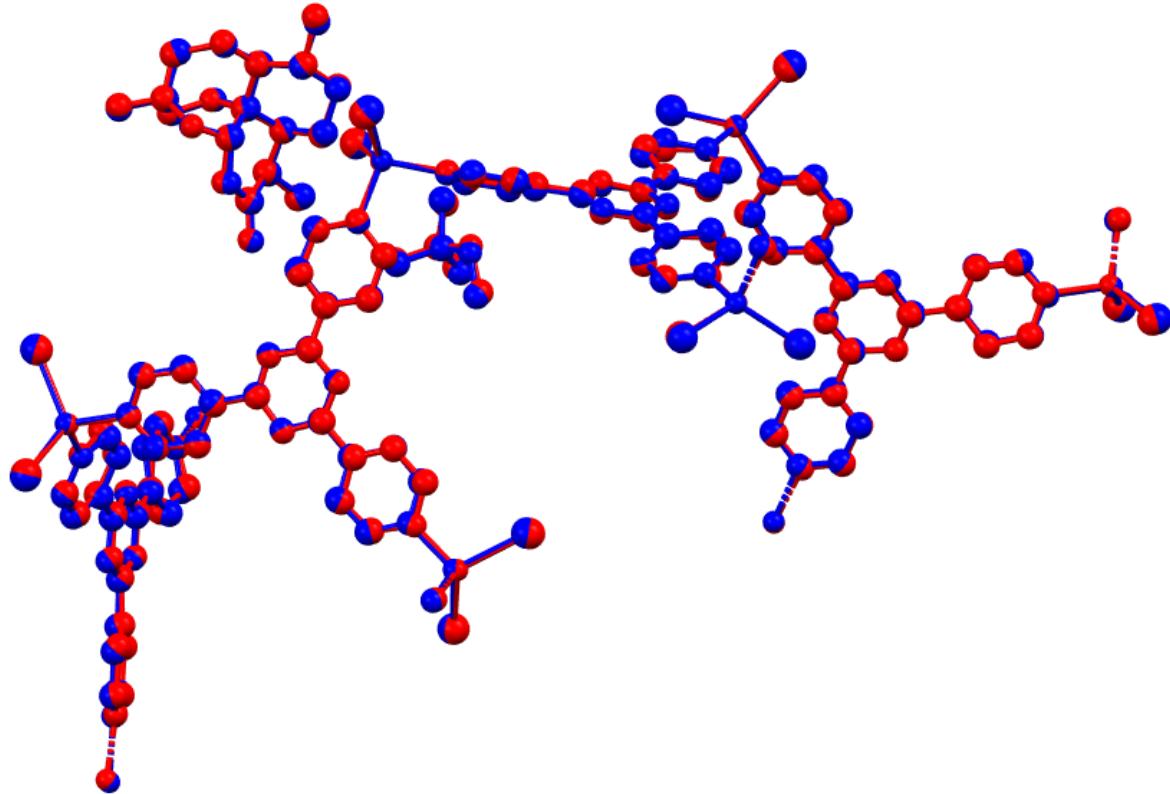

Figure S2. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of 4-(trifluoromethyl)phenyl azide@**1a**. Hydrogen atoms have been omitted.

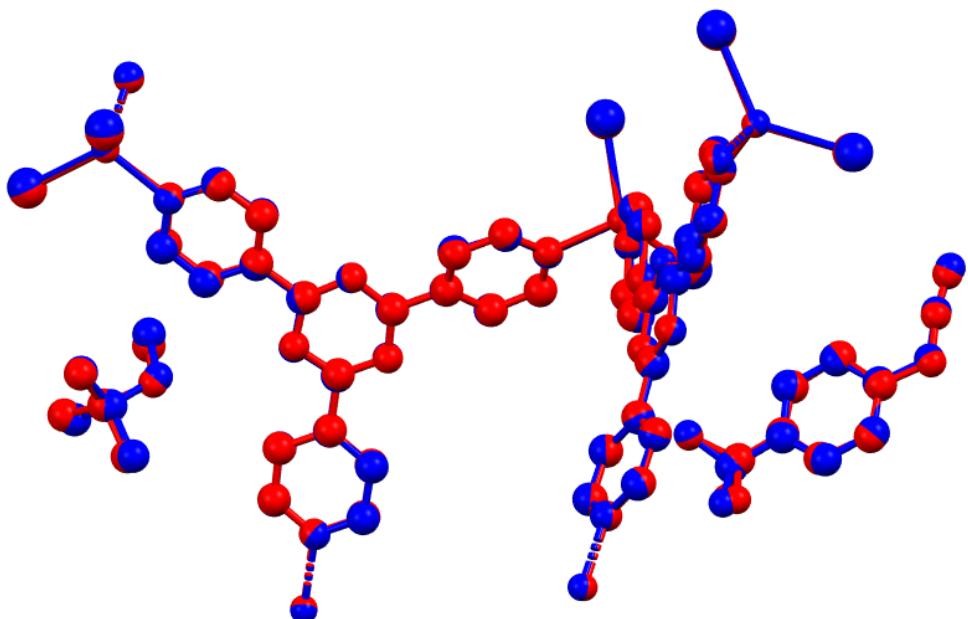

Figure S3. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of vanillin@**1a**. Hydrogen atoms have been omitted.

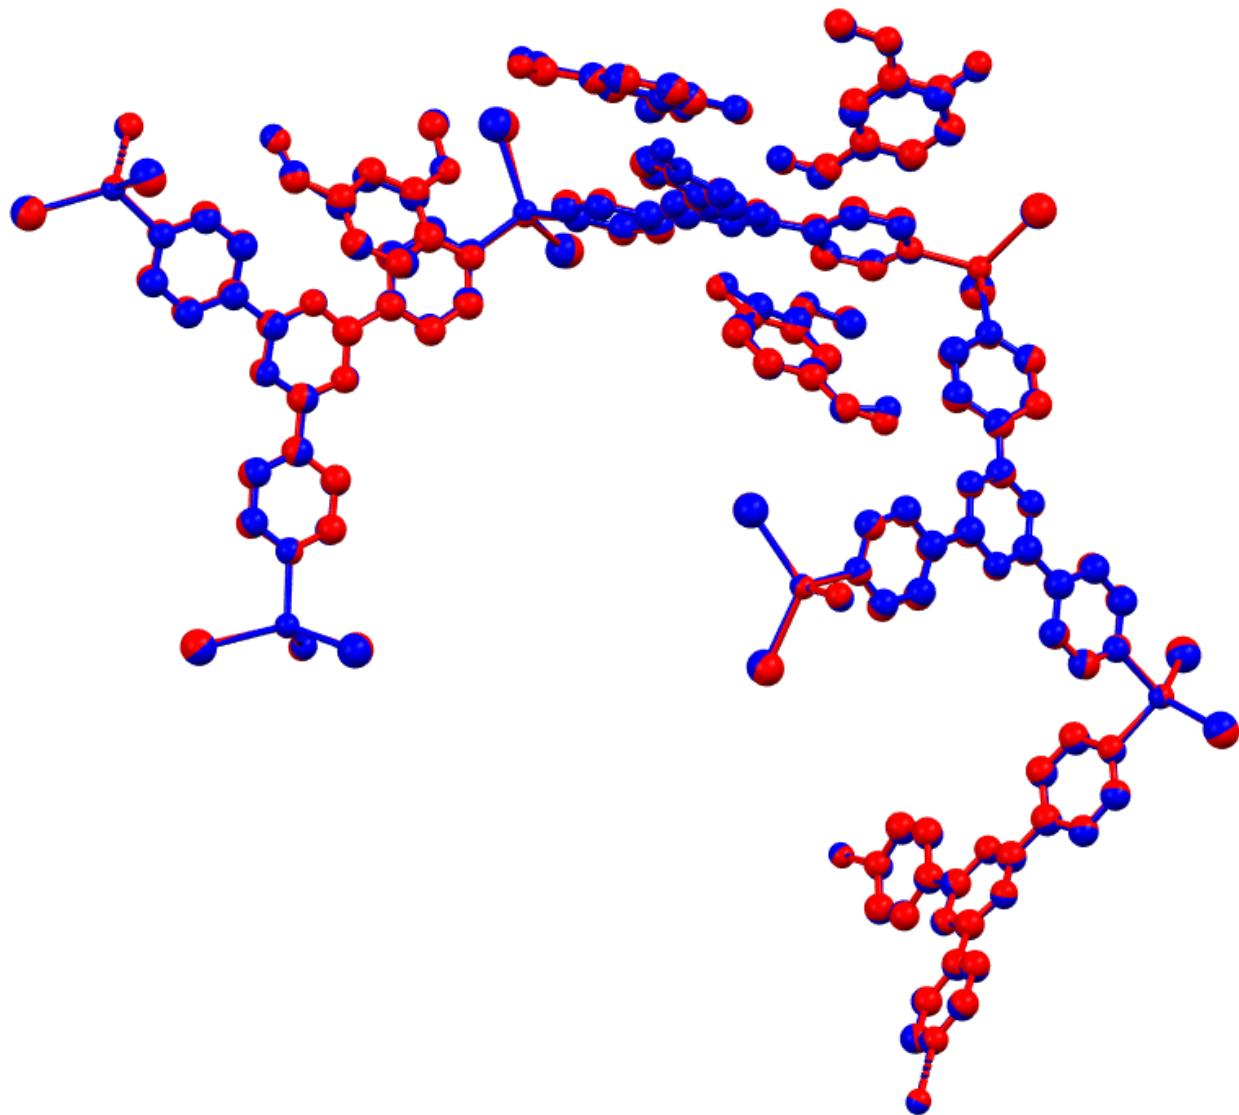

Figure S4. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of (*1R*)-(-)-menthyl acetate@**1b**. Hydrogen atoms have been omitted.

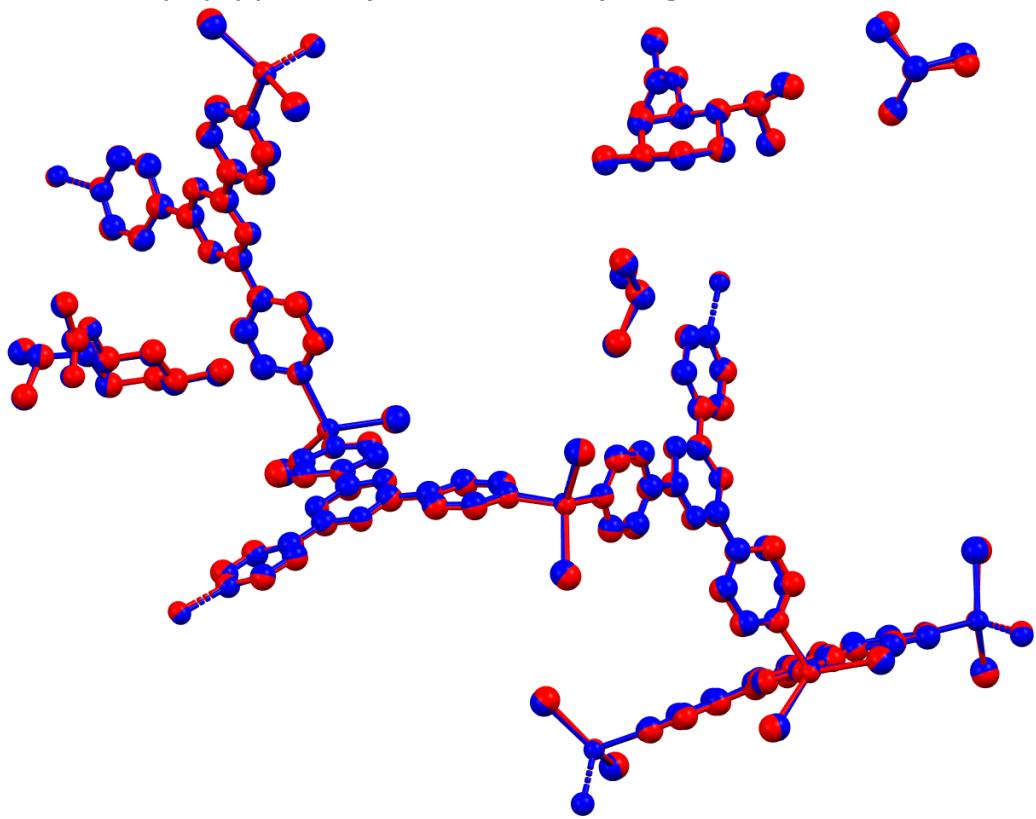

Figure S5. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of (*1R*)-(-)-menthyl acetate@**1c**. Hydrogen atoms have been omitted.

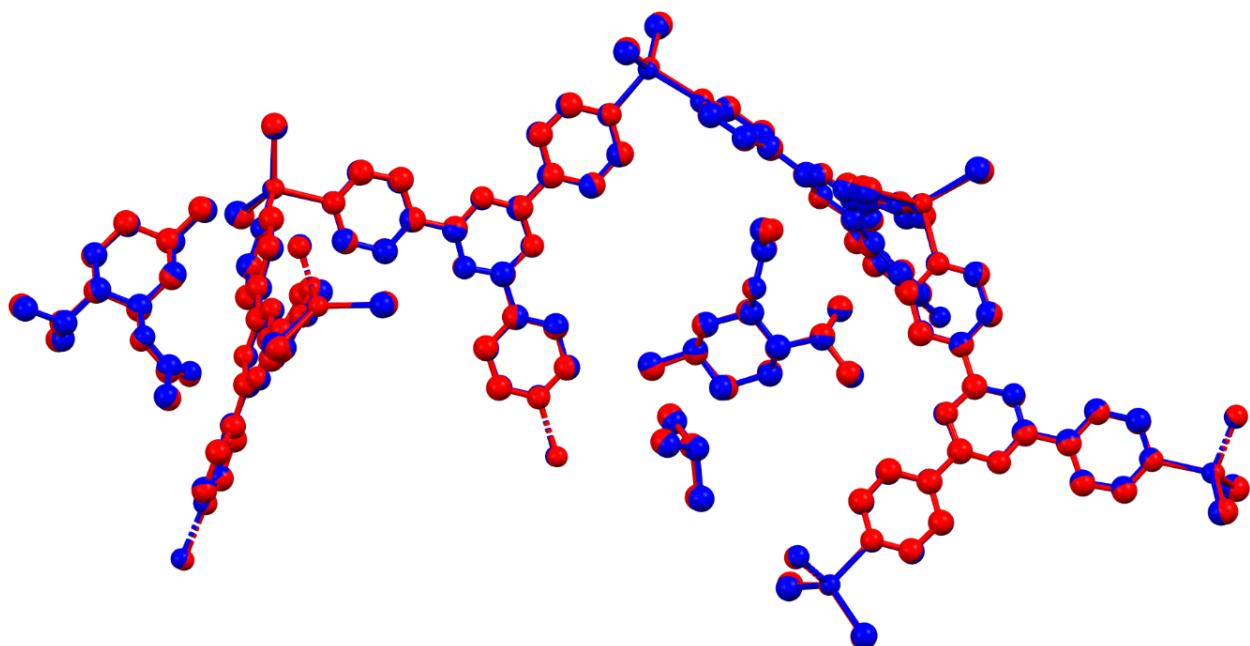

Figure S6. Overlay of the experimental (blue) and computationally geometry optimised (red) structures of chloroform@**1a**. Hydrogen atoms have been omitted.

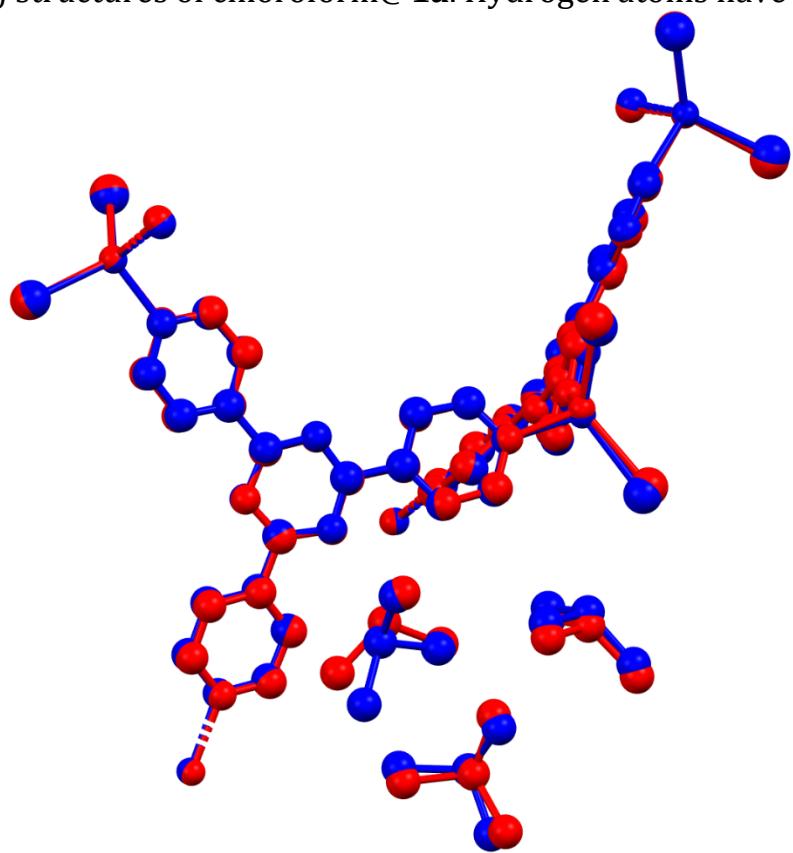

Figure S7. Experimental crystallographic packing model illustrating possible contacts (in Å) forged by A (centre) in *trans*-anethole@**1a**. Extraneous atoms are hidden for clarity. The starred methyl group in the analysed target forges a possible 3.92(2) Å contact with a foreground host iodine atom that is not shown due to an obstructed view. Guest ellipsoids are shown at 50% probability.

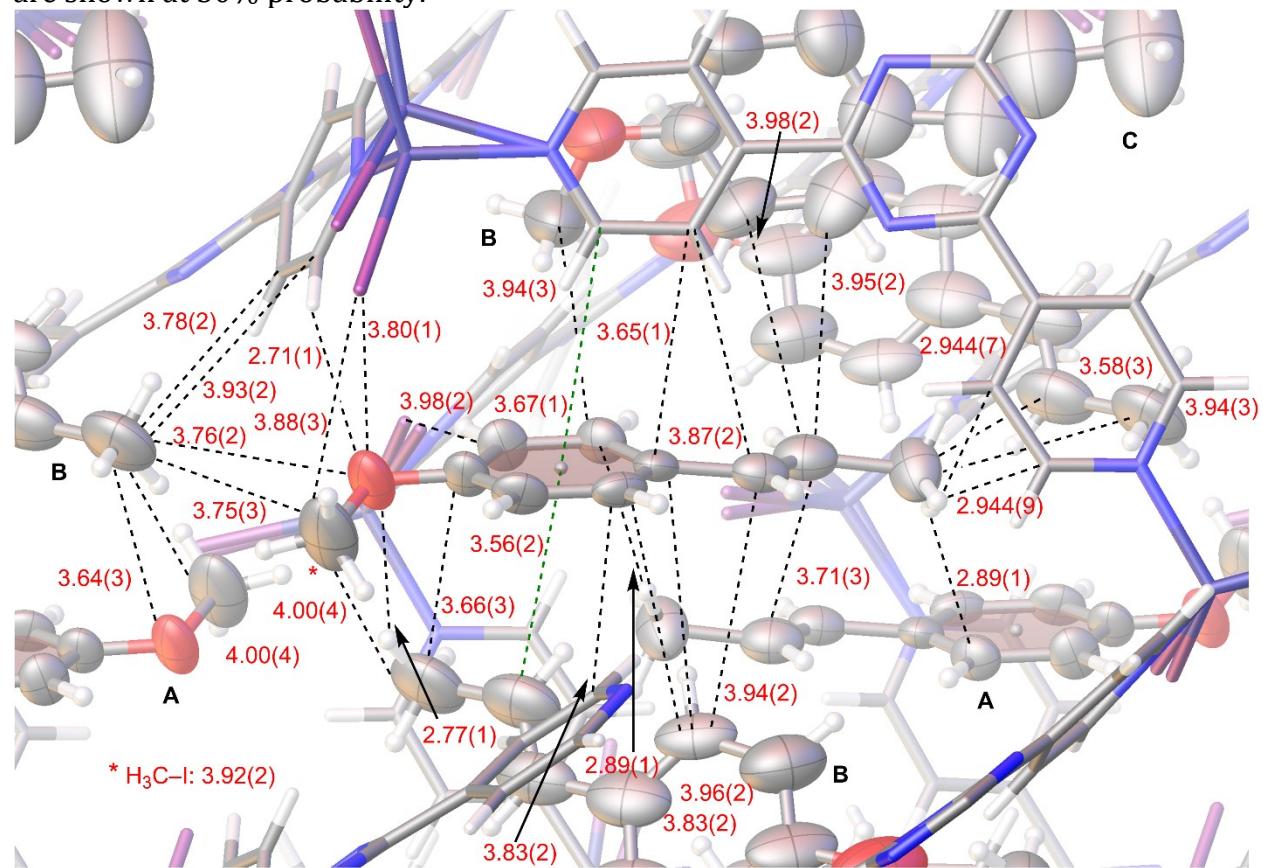

Figure S8. Experimental crystallographic packing models illustrating possible contacts (in Å) forged by (a) E in (+)-artemisinin@**1a** and (b) G in 4-(trifluoromethyl)phenyl azide@**1a**. Extraneous atoms are hidden for clarity. Guest ellipsoids are shown at 50% probability.

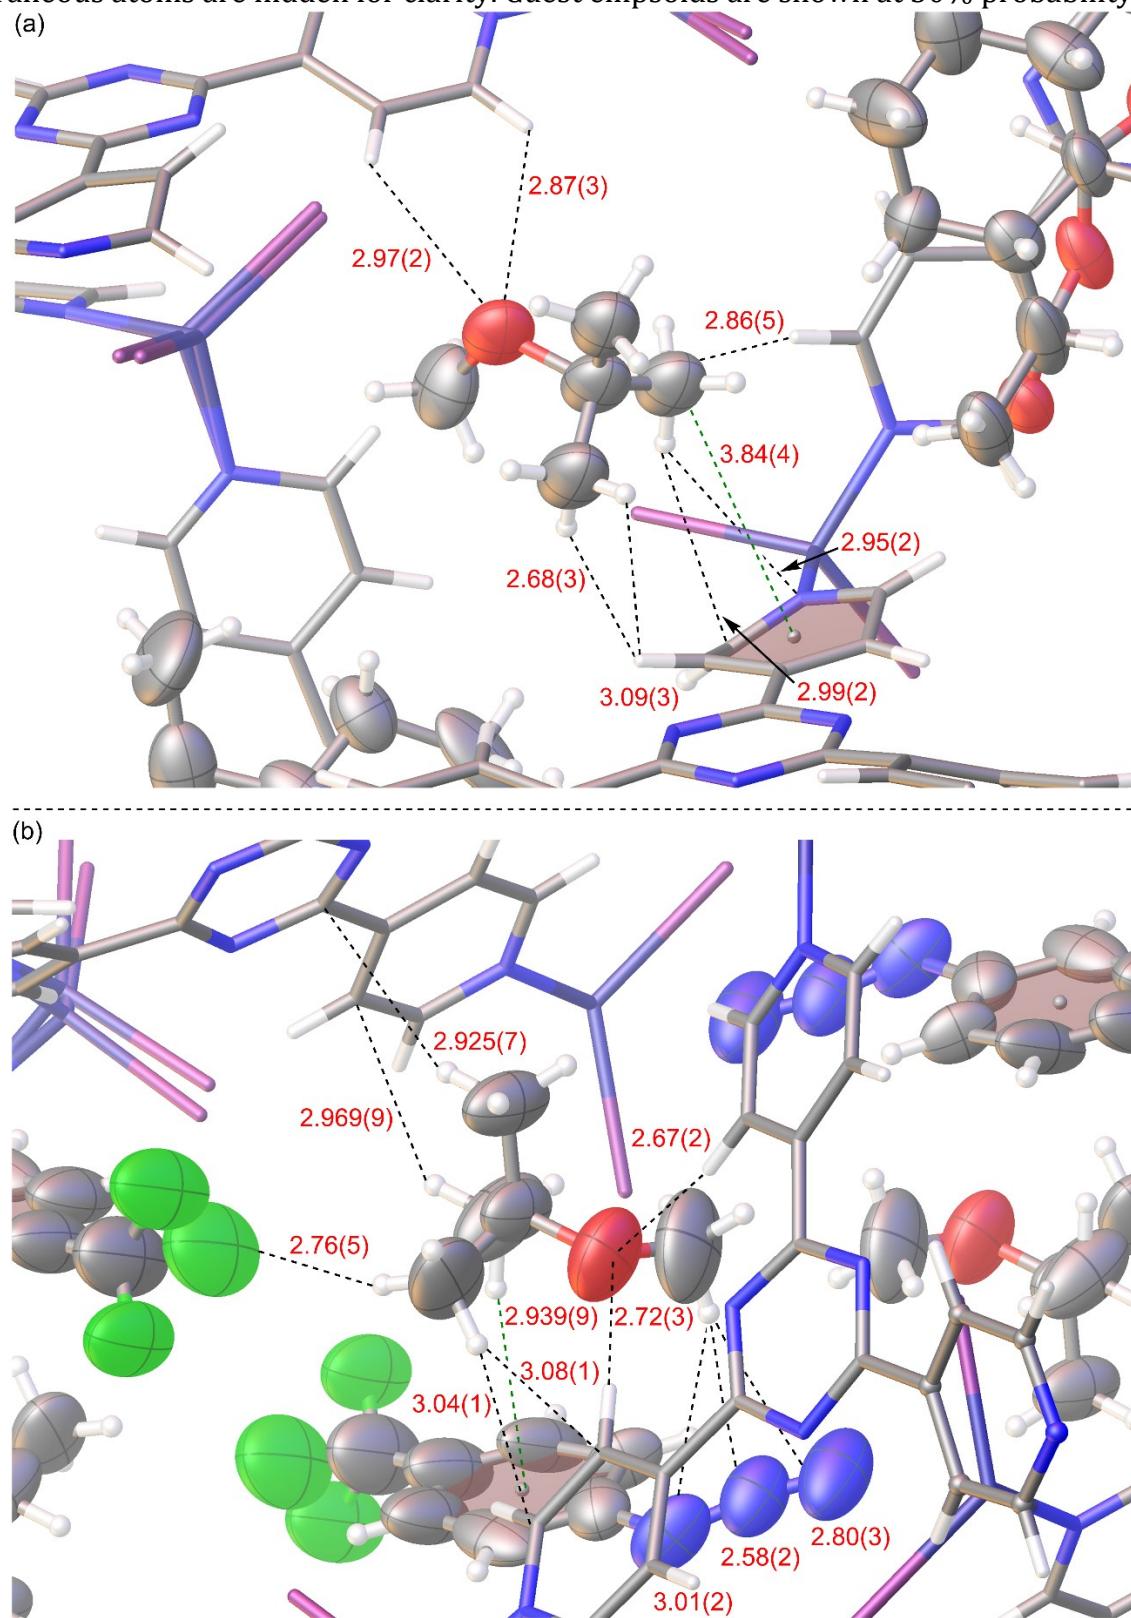

Figure S9. Experimental crystallographic packing model illustrating possible contacts (in Å) forged by **H** in vanillin@**1a**. Extraneous atoms are hidden for clarity. Guest ellipsoids are shown at 50% probability.

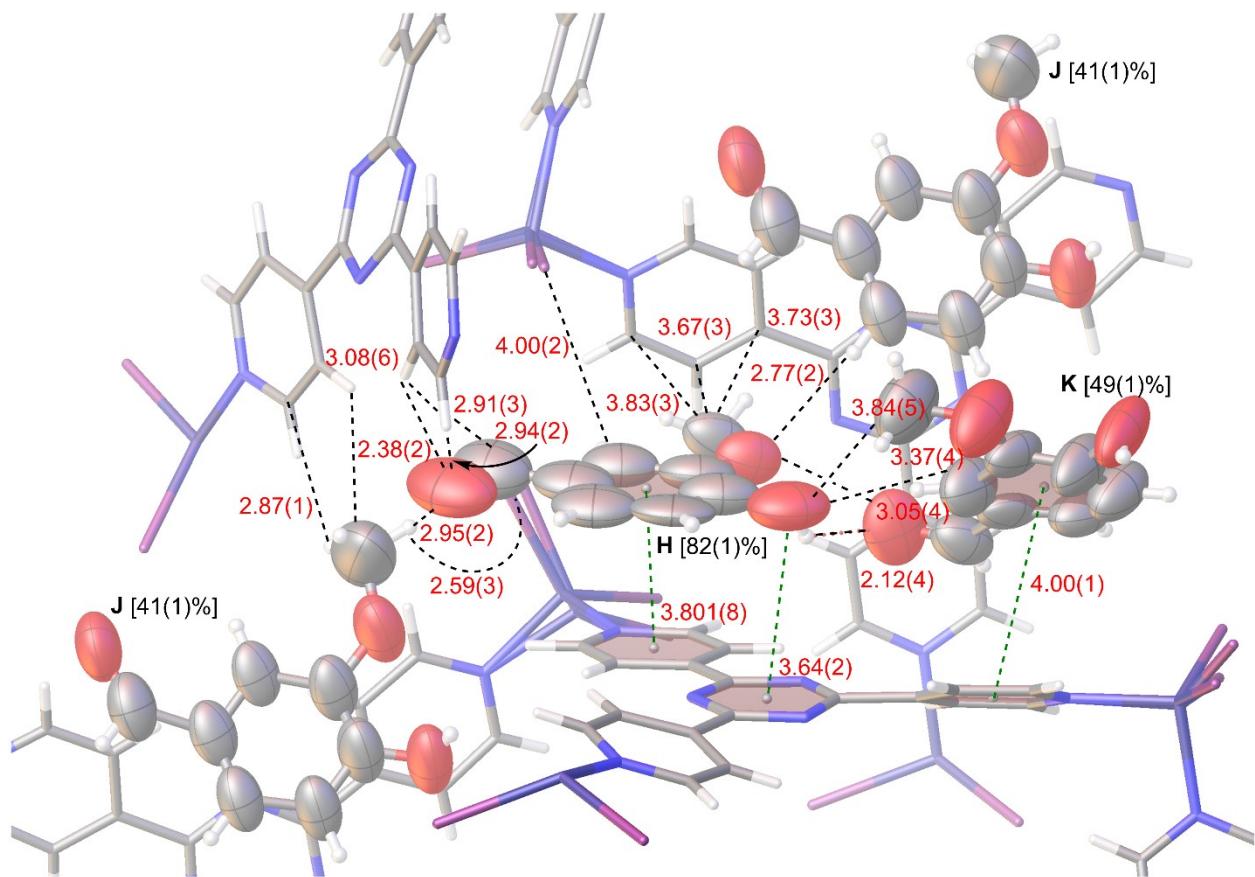

Figure S10. Experimental crystallographic packing model illustrating possible contacts (in Å) forged by **K** (centre) in vanillin@**1a**. Extraneous atoms are hidden for clarity. Guest ellipsoids are shown at 50% probability.

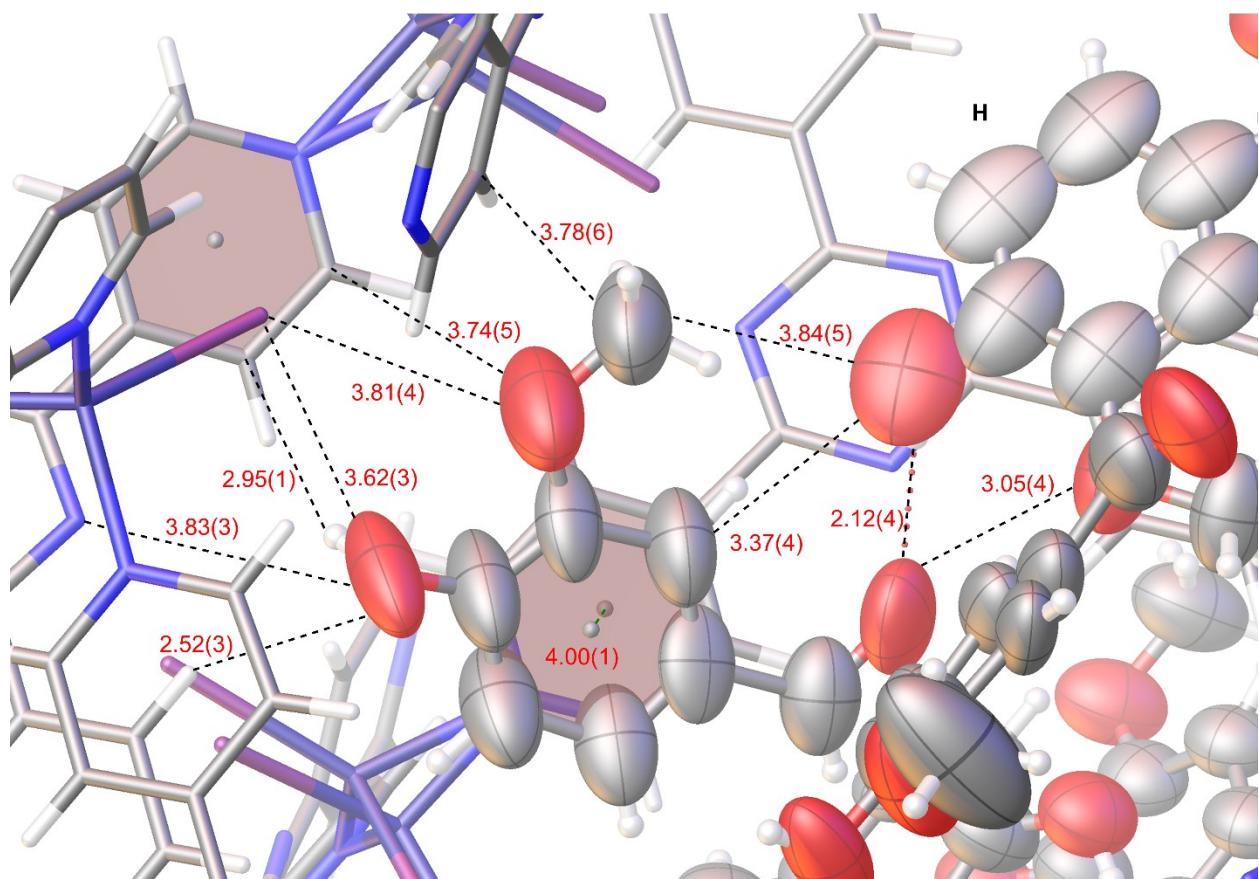

Figure S11. Experimental crystallographic packing models illustrating possible contacts (in Å) in (1*R*)-(-)-menthyl acetate@**1b** forged by (a) N and (b) O. Extraneous atoms are hidden for clarity. Guest ellipsoids are shown at 50% probability.

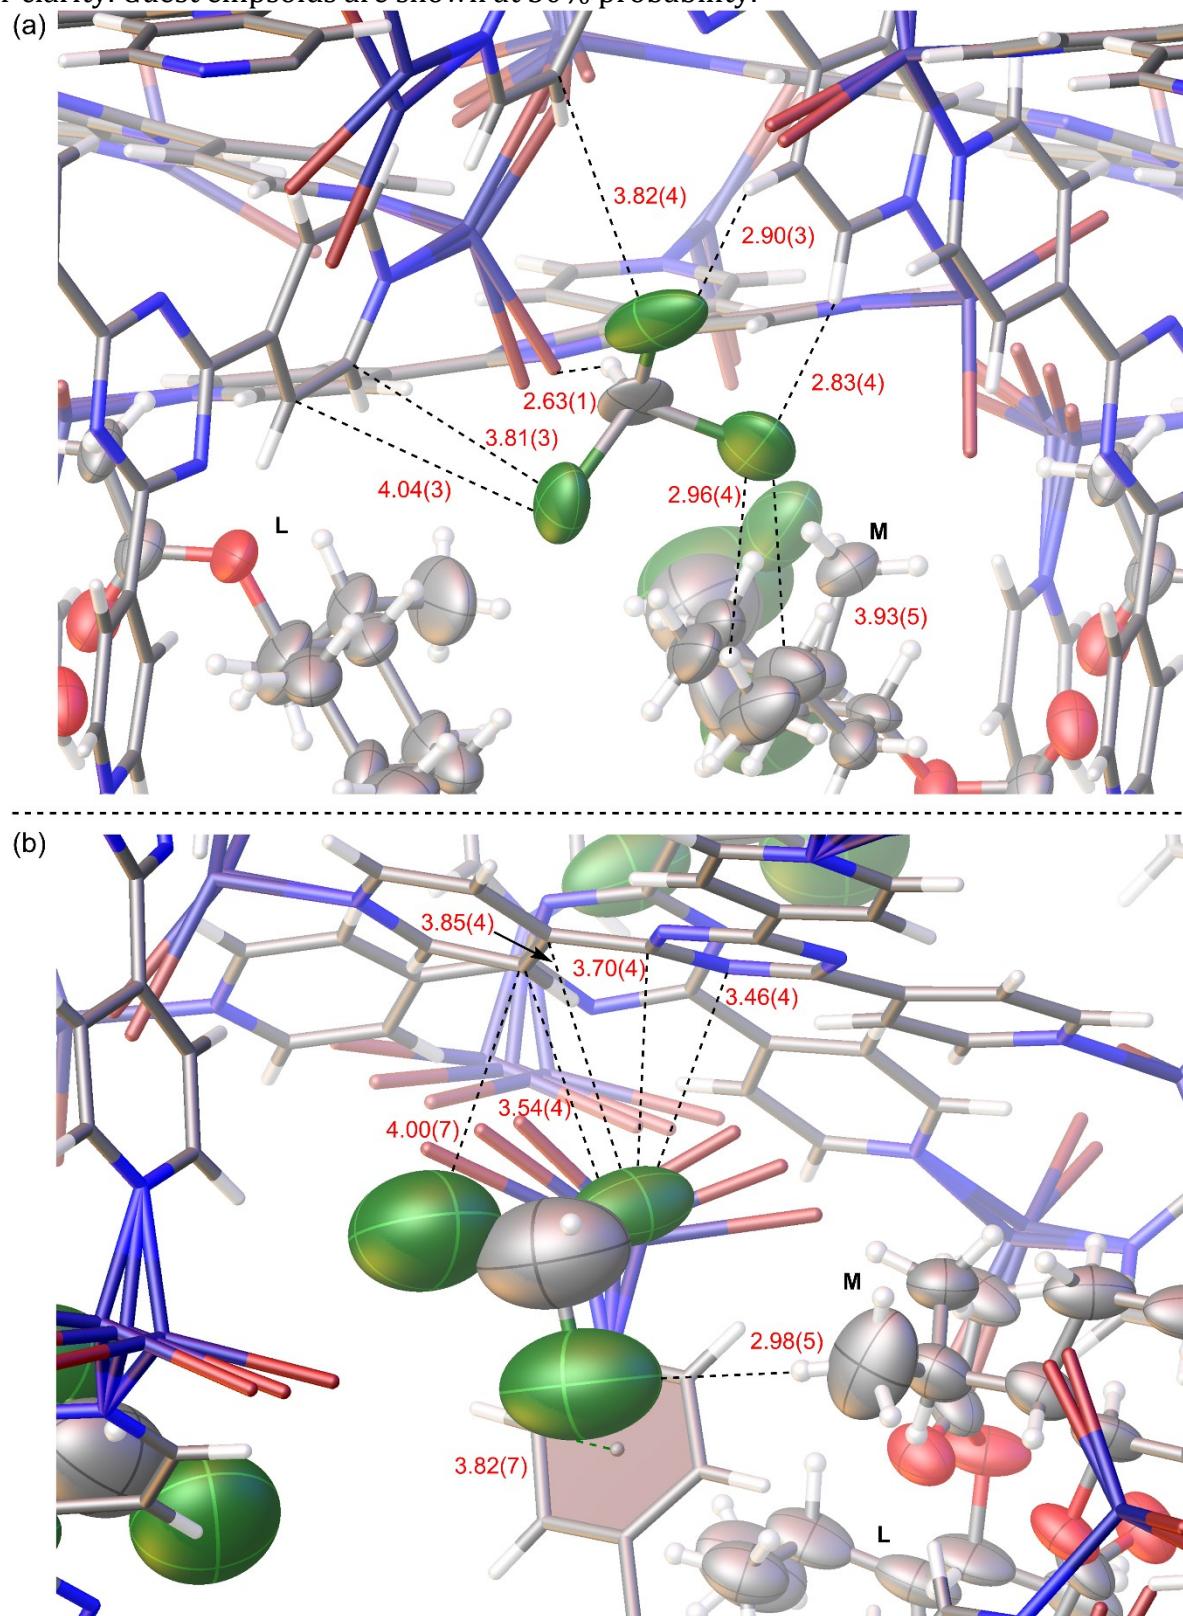

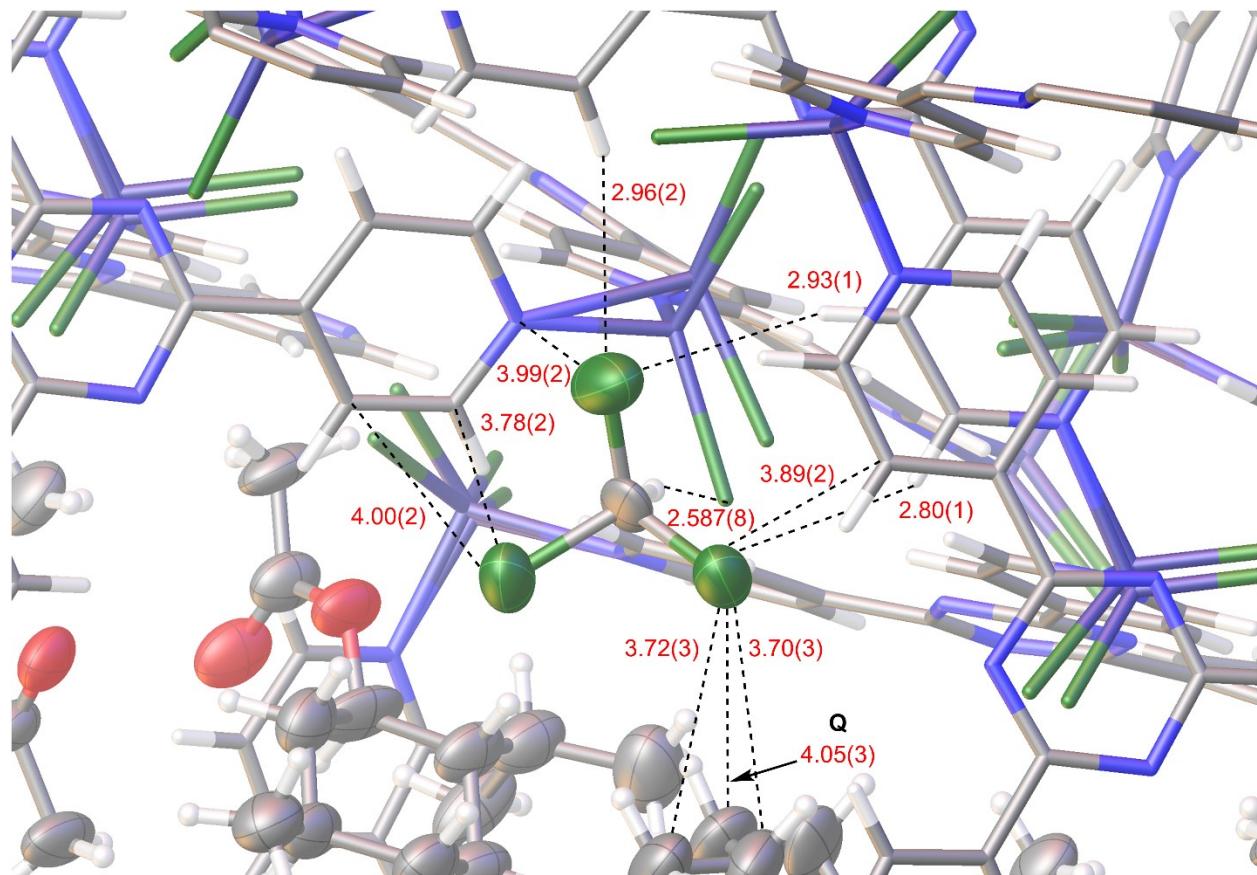

Figure S12. Experimental crystallographic packing model illustrating possible contacts (in Å) forged by **R** in (1*R*)-(-)-menthyl acetate@**1c**. Extraneous atoms are hidden for clarity. Guest ellipsoids are shown at 50% probability.
