## I. Kinetic model for the *syn*-CH<sub>3</sub>CHOO + CH<sub>2</sub>=CHCHO reaction

The formation of *syn*-CH<sub>3</sub>CHOO includes reactions listed below:

The consumption of *syn*-CH<sub>3</sub>CHOO results from the following reactions:

Reaction (R7) describes the consumption of OH:

Where X in reaction (R12) denotes the species that react with *syn*-CH<sub>3</sub>CHOO, such as I and CH<sub>3</sub>CHI<sub>2</sub>. Y in reaction (R14) denotes the species that consume the OH, e.g., IO, CH<sub>3</sub>CHI<sub>2</sub>, CH<sub>3</sub>CHO, and CH<sub>2</sub>=CHCHO. We neglected the cross-self-reaction of *syn*-CH<sub>3</sub>CHOO with *anti*-CH<sub>3</sub>CHOO as it is hardly discernible under similar experimental condition.<sup>1</sup>

The OH(*v*'=0) decay profiles were fitted with the expression (II) (for details see our previous publication)<sup>2</sup>:

$$S_{\text{OH}} = \frac{A_0(k_{10} + k'_{11} + k'_{12})}{(k_{10} + k'_{11} + k'_{12})e^{(k_{10} + k'_{11} + k'_{12})t} + 2k_{13}[\textit{syn}\text{-CH}_3\text{CHOO}]_0(e^{(k_{10} + k'_{11} + k'_{12})t} - 1)} - A_1e^{-k'_{14}t} \quad (\text{SI})$$

where  $A_0 = \gamma \frac{k_{10a}[\textit{syn}\text{-CH}_3\text{CHOO}]_0}{k'_{14} - (k_{10} + k'_{11} + k'_{12})}$ ,  $A_1 = \gamma \left( \frac{k_{10a}[\textit{syn}\text{-CH}_3\text{CHOO}]_0}{k'_{14} - (k_{10} + k'_{11} + k'_{12})} - [\text{OH}]_0 \right)$ .

In expression (II),  $k'_{11} = k_{11}[\text{CH}_2=\text{CHCHO}]$ ;  $k'_{12} = k_{12}[\text{X}]$ ;  $k'_{13}$  was fixed to a reported value of  $1.6 \times 10^{-10} \text{ cm}^3 \text{ s}^{-1}$ ,  $k'_{14} = k_{14}[\text{Y}]$ . The initial concentration of *syn*-CH<sub>3</sub>CHOO,  $[\textit{syn}\text{-CH}_3\text{CHOO}]_0$ , was fixed to

a calculated value during the fitting.  $[\text{OH}]_0$  is the concentration of OH from the decomposition of energized  $\text{CH}_3\text{CHOO}$ ;  $\gamma$  is the OH detection efficiency.

## II. Summary of experimental conditions

**Table S1.** Summary of the experimental conditions for  $\text{CH}_2\text{OO}$  reaction with  $\text{CH}_2=\text{CHCHO}$  at different temperatures. The total pressure is 10 Torr;  $[\text{CH}_2\text{I}_2] \sim (1.54 \pm 0.18) \times 10^{14} \text{ cm}^{-3}$ ;  $[\text{CH}_2\text{OO}] \sim (3.59 \pm 0.86) \times 10^{12} \text{ cm}^{-3}$ ;  $[\text{O}_2] = 2.50 \times 10^{16} \text{ cm}^{-3}$ ;  $I_{248} \sim 15 \text{ mJ cm}^{-2}$ .

### III. Error analysis

The overall errors for the rate coefficients  $k_5$  and  $k_{11}$ , as shown in Table S1 and S2, are determined as follow:

#### a) The estimation of $[\text{CH}_2\text{OO}]_0$ and $[\text{syn-CH}_3\text{CHOO}]_0$

$[\text{CH}_2\text{OO}]_0$  and  $[\text{syn-CH}_3\text{CHOO}]_0$  was calculated as  $y \times f \times b \times [\text{CH}_2\text{I}_2]_0$  (or  $[\text{CH}_3\text{CHI}_2]_0$ ).

$y$  is the fraction of  $\text{CH}_2\text{I}_2/\text{CH}_3\text{CHI}_2$  that were photolyzed by 248 nm laser and it was calculated as  $(F/h\nu_{248}) \times \sigma_{248}$ .  $F$  denotes the laser fluence (0.5 cm beam diameter), and  $\sigma_{248}$  is the absorption cross-section of  $\text{CH}_2\text{I}_2/\text{CH}_3\text{CHI}_2$  at 248 nm ( $1.61 \times 10^{-18}$  and  $1.57 \times 10^{-18}$   $\text{cm}^2 \text{ molecule}^{-1}$ ).<sup>3</sup> In the current experimental condition,  $y$  is about 3%.

$f$  is the fractional yield of  $\text{CH}_2\text{OO}/\text{CH}_3\text{CHOO}$  from the reaction of  $\text{CH}_2\text{I}/\text{CH}_3\text{CHI}$  with  $\text{O}_2$ , which was pressure-dependent.<sup>4</sup> The yield of  $\text{CH}_2\text{OO}$  was reported to be ca. 0.76 at 7.6 Torr and 0.52 at 200 Torr.<sup>4</sup> For the  $\text{CH}_3\text{CHOO}$ , the fractional yield was reported as  $0.86 \pm 0.11$  at 2 Torr<sup>5</sup> and 0.9 at pressures between 5 and 20 Torr,<sup>6</sup> but no available knowledge about the  $f$  at higher pressure was reported and therefore we adopted a value of 0.9 for  $f$  at 5-150 Torr pressure range.

$b$  is the ratio of  $[\text{syn-CH}_3\text{CHOO}]$  to  $[\text{CH}_3\text{CHOO}]$  (the existence of *anti-CH}\_3\text{CHOO}*). This value was estimated to be 0.7.<sup>6</sup> This value is 1 for  $\text{CH}_2\text{OO}$ .

The  $[\text{CH}_2\text{I}_2]_0 / [\text{CH}_3\text{CHI}_2]_0$  was measured by a deep UV LED (DUV325-H46, Roithner Lasertechnik, centered at 322.4 nm) and a balanced amplified photodetector (PDB450A, Thorlabs), with known absorption cross-section and LED emission profile.

#### b) Error analysis

Considering errors in the measurement of flow rate (1%), pressure (3%), temperature (1%), the fluence of the LED light source (10%) and the UV absorption cross-section of  $\text{CH}_2\text{I}_2$  (5%), we estimated the errors of  $[\text{CH}_2\text{I}_2]$  to be 12%. With the errors of the fractional yield of  $\text{CH}_2\text{OO}$  from the  $\text{CH}_2\text{I} + \text{O}_2$  reaction (20%), the fluence of photolysis laser (5%), the UV absorption cross-section of  $\text{CH}_2\text{I}_2$  at 248 nm (5%) and  $[\text{CH}_2\text{I}_2]$  (12%), the uncertainty of  $[\text{CH}_2\text{OO}]_0$  was calculated to be 24%.

Similarly, considering the errors of  $[\text{CH}_3\text{CHI}_2]$  (12%), the errors of the fractional yield of  $\text{CH}_3\text{CHOO}$  from the  $\text{CH}_3\text{CHI} + \text{O}_2$  reaction (20%), the branching of *syn-CH}\_3\text{CHOO}* (20%), the fluence of photolysis laser (5%), and the UV absorption cross-section of  $\text{CH}_3\text{CHI}_2$  at 248 nm (5%). we estimated the uncertainty of  $[\text{syn-CH}_3\text{CHOO}]_0$  to be 31%.

During fitting the OH decay profiles, the  $\text{CH}_2\text{OO}$  self-reaction rate coefficient,  $k_4$ , was fixed to  $8 \times 10^{-11}$   $\text{cm}^3 \text{ s}^{-1}$ , the uncertainty of which was estimated to be 50%.<sup>4</sup> And the *syn-CH}\_3\text{CHOO}* self-reaction rate coefficient was fixed to  $1.6 \times 10^{-10}$   $\text{cm}^3 \text{ s}^{-1}$  with uncertainty of 33%.<sup>1</sup> Therefore, the error of  $[\text{CH}_2\text{OO}]_0 \times$

$k_4$  and  $[\text{syn-CH}_3\text{CHOO}]_0 \times k_{13}$  is about 56% and 46%, respectively. Table S3 and S4 shows the values of  $k_5$  and  $k_{11}$  when varying the value of  $[\text{CH}_2\text{OO}]_0 \times k_4$  and  $[\text{syn-CH}_3\text{CHOO}]_0 \times k_{13}$ . According to Table S2 and S3, we estimated the error of  $k_5$  and  $k_{11}$  caused by the uncertainty of  $[\text{CH}_2\text{OO}]_0 \times k_4$  and  $[\text{syn-CH}_3\text{CHOO}]_0 \times k_{13}$  to be 5% and 8%, respectively.

For the reaction of  $\text{CH}_2\text{OO}$  with  $\text{CH}_2=\text{CHCHO}$ , considering the errors from fitting the OH decay profiles (5%), the linear fits (1%-14%) that depend on the total pressure, the absolute  $[\text{CH}_2=\text{CHCHO}]$  (10%) and the error of  $k_5$  caused by the uncertainty of  $[\text{CH}_2\text{OO}]_0 \times k_6$  (5%), the overall error of  $k_5$  was estimated to be 12-19%. Similarly, we estimated the overall error of the  $k_{11}$  for the reaction of *syn*- $\text{CH}_3\text{CHOO}$  with  $\text{CH}_2=\text{CHCHO}$  to be 15-20%.

**Table S3.** The error of  $k_5$  resulting from the 56% uncertainty of  $[\text{CH}_2\text{OO}]_0 \times k_4$ .

| Exp #          | $[\text{CH}_2\text{OO}]_0 \times k_4 / \text{s}^{-1}$ | $[\text{CH}_2\text{OO}]_0 \times k_4 \times (1 \pm 56\%) / \text{s}^{-1}$ | $k_5 / 10^{-12} \text{ cm}^3 \text{ s}^{-1}$ | $k_5 / 10^{-12} \text{ cm}^3 \text{ s}^{-1}$ | Uncertainty / %  |

<sup>a</sup> The data highlighted in yellow shows the values and uncertainties of  $k_{13}$  when fixing the  $[\text{syn-CH}_3\text{CHOO}]_0 \times k_{13}$  to its upper-limit value,  $(1.46 \times [\text{syn-CH}_3\text{CHOO}]_0 \times k_{13})$ .

<sup>b</sup> The data highlighted in grey shows the values and uncertainties of  $k_{13}$  when fixing the  $[\text{syn-CH}_3\text{CHOO}]_0 \times k_{13}$  to its lower-limit value,  $(0.54 \times [\text{syn-CH}_3\text{CHOO}]_0 \times k_{13})$ .

#### IV. Sensitivity analysis of the fit on $A_1$ and $k'_{14}$

During fits the OH time-dependent profiles of *syn*-CH<sub>3</sub>CHOO + CH<sub>2</sub>=CHCHO reaction, the parameters of  $A_0$ ,  $A_1$ ,  $k_{10} + k'_{11} + k'_{12}$  (corresponding to the  $k_3 + k'_5 + k'_6$  in the CH<sub>2</sub>OO + CH<sub>2</sub>=CHCHO reaction), and  $k'_{14}$  (the overall loss rate of OH) were floated. The fits are not sensitive to either  $A_1$  or  $k'_{14}$ , as shown in Table S5-S7.

OH is expected to be consumed mainly by reacting with CH<sub>3</sub>CHI<sub>2</sub> and acrolein. Thus, the predicted  $k'_{14}$  value can be calculated as follows:

$$k'_{14} = k_{\text{CH}_3\text{CHI}_2}[\text{CH}_3\text{CHI}_2] + k_{\text{acrolein}}[\text{acrolein}] \quad (\text{SII})$$

where, the  $k_{\text{CH}_3\text{CHI}_2}$  and  $k_{\text{acrolein}}$  are the rate coefficient for OH + CH<sub>3</sub>CHI<sub>2</sub> and OH + acrolein reaction, respectively.  $k_{\text{CH}_3\text{CHI}_2}$  is not available; we take the rate coefficient for OH + CH<sub>2</sub>I<sub>2</sub> reaction(  $(4.45 \pm 0.32) \times 10^{-12} \text{ cm}^3 \text{ s}^{-1}$  ) as a reference.<sup>7</sup> The values of  $k_{\text{acrolein}}$  was reported to be  $(1.99 \pm 0.24) \times 10^{-11} \text{ cm}^3 \text{ s}^{-1}$ .<sup>8</sup>

The fitted values of  $A_0$ ,  $A_1$ ,  $k_{10} + k'_{11} + k'_{12}$ —with  $k'_{14}$  floated or fixed to the calculated values—are listed in Table S5. It shows that the fitted values of  $A_0$  and  $k_{10} + k'_{11} + k'_{12}$  did not change when  $k'_{14}$  were either floated or fixed to calculated values. This is because the decrease portion of OH profiles is mainly described by the first term of eqn (SI).<sup>2</sup> Table S5 also shows that the output values of  $A_1$  are exceptionally small when  $k'_{14}$  were fixed to calculated values. This could be because the fits are not sensitive to  $A_1$ . We fixed  $k'_{14}$  to calculated values and fixed  $A_1$  to different values, as shown in Table S6 and Table S7. It shows that the  $k_{10} + k'_{11} + k'_{12}$  barely change when increasing  $A_1$  from 0 to 500 ( $[\text{acrolein}] \sim 0.37 \times 10^{15} \text{ cm}^{-3}$ ) and 0 to 5000 ( $[\text{acrolein}] \sim 2.4 \times 10^{15} \text{ cm}^{-3}$ ).

**Table S5.** The fitted values of  $A_0$ ,  $A_1$ ,  $k_{10} + k_{11} + k_{12}$ —with  $k'_{14}$  floated or fixed to the calculated values. The total pressure is 15 Torr;  $[\text{CH}_3\text{CHI}_2] \sim (1.30 \pm 0.16) \times 10^{14} \text{ cm}^{-3}$ ;  $[\text{syn-CH}_3\text{CHOO}] \sim (2.44 \pm 0.75) \times 10^{12} \text{ cm}^{-3}$ ;  $[\text{O}_2] = 2.50 \times 10^{16} \text{ cm}^{-3}$ ;  $I_{248} \sim 15 \text{ mJ cm}^{-2}$ .
