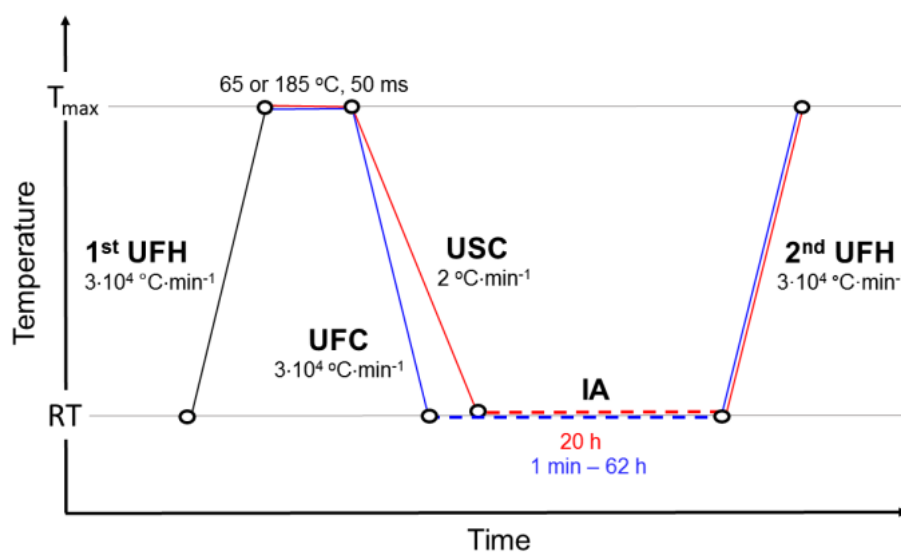

**Fig. S1** Pulse sequence diagram of the SE signal (A) and normalized SE decays of TPU-IPDI recorded in crystallization at 20 °C after cooling from 150 °C (B).

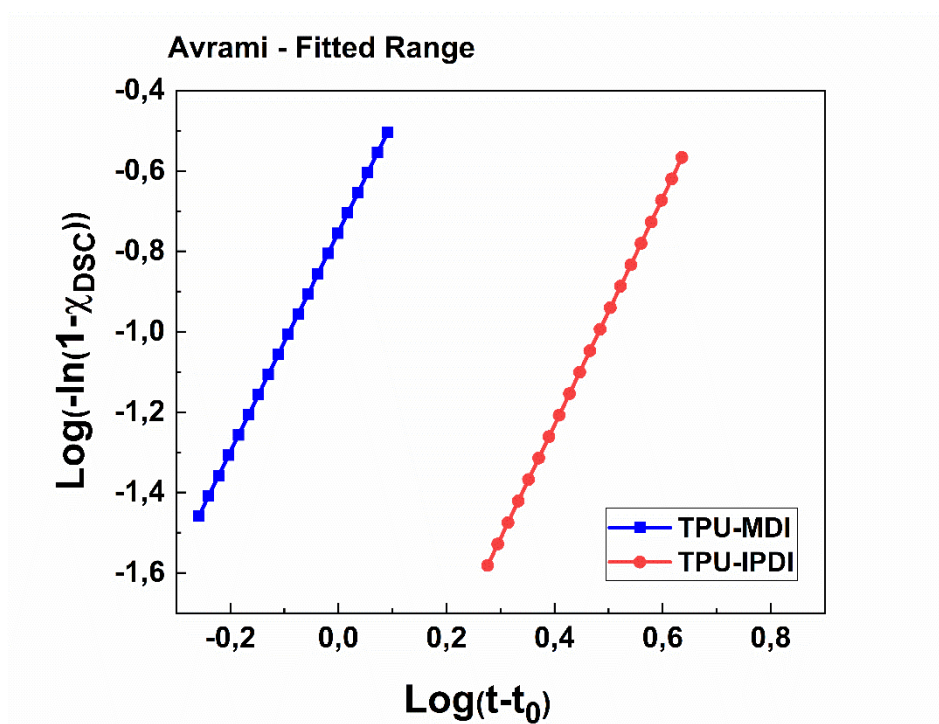

The solid-state echo decay pulse train consists of a 90° at RT pulse in the x direction followed by a 90° pulse in the y direction after a delay time  $\tau$ . Continuously increasing  $\tau$  and registering the maximum of the echo signal by  $2\tau$ , at the top of which a conditional zero is established, the decay of the transverse magnetization is recorded.

**Fig. S2** Experimental and fitted dependence of the Free Induction Decays (FID) of a two-step damping form Gaussian to exponential due to differences in the segmental mobility of the rigid and amorphous phases.

**Fig. S3** Temperature programs for nanocalorimetric measurements: Program 1 (black line), Program 2 (red lines) and Program 3 (blue lines).

**Fig. S4** Time dependence of  $\chi_{\text{DSC}}$  in Avrami coordinates for TPU-MDI (blue curve) and TPU-IPDI (red curve).

**Fig. S5** Changes in the spin-spin relaxation time  $T_{2s}$  during crystallization at 20 °C after cooling from 150 °C.

Normally, the general trend in relaxation time of a rigid fraction with cooling and crystallizing should show the decrease of  $T_{2s}$ . For the sample TPU-HMDI we observe definitely reversed behavior that can be explained by more intensive magnetization exchange between crystals and amorphous regions due to presence of in intermediate mesophase.

**Table S1** Main frequencies and assignments of FTIR bands to crystal phases of PBA oligodiol.

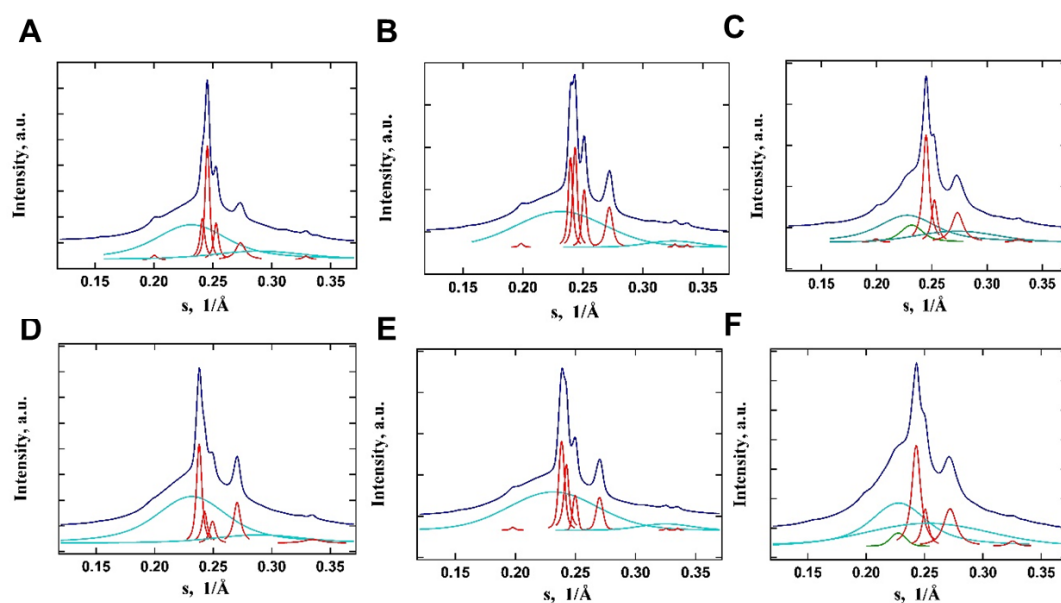

Main assignment	Wavenumber, $\text{cm}^{-1}$	Phase	Wavenumber, $\text{cm}^{-1}$	Phase	Wavenumber, $\text{cm}^{-1}$	Phase
	20 °C/min		2 °C/min		storage at RT	
$\gamma$ CH <sub>2</sub>	911	$\beta$	908	$\alpha$	908	$\alpha$
$\gamma$ CH <sub>2</sub>	930	$\beta$	-	$\alpha$	-	$\alpha$
$\gamma$ CH <sub>2</sub>	958	$\beta$	957	$\alpha$	957	$\alpha$
$\sigma_s$ CH <sub>2</sub>	1371	$\beta$	1368	$\alpha$	1368	$\alpha$
$\sigma_{as}$ CH <sub>2</sub>	1401	$\beta$	1398	$\alpha$	1398	$\alpha$
$\delta_s$ CH <sub>2</sub>	1416	$\beta$	1418	$\alpha$	1418	$\alpha$
$\delta_{as}$ CH <sub>2</sub>	1464	$\beta$	1461	$\alpha$	1461	$\alpha$
$\nu_{as}$ C-O-C	1258	$\beta$	1257	$\alpha$	1257	$\alpha$
$\nu_s$ C-O	1162	$\beta$	1160	$\alpha$	1160	$\alpha$

Thus, it has been established that upon 20 °C/min cooling, the pure  $\beta$ -form crystallizes, while upon 2 °C/min cooling, the pure  $\alpha$ -form crystallizes («fresh»). Storage («old») of PBA at RT leads to the formation of the  $\alpha$ -phase.

**Table S2** Main frequencies and assignments of FTIR bands to crystal phases of PBA in TPUs.

Main assignment	wavenumber, $\text{cm}^{-1}$	phase	wavenumber, $\text{cm}^{-1}$	phase	wavenumber, $\text{cm}^{-1}$	phase

\*UFH/UFC – ultra-fast heating/cooling with rate of 30 000 °C/min

\*\*heating of the initial sample from RT to 185 °C

SC – slow cooling with rate of 20 °C/min

USC – ultra-slow cooling with rate of 2 °C/min

**Fig. S9** DSC heating curves up to 150 °C of the initial films (1st heating, black curves) and after 30-min crystallization at 20 °C (2nd heating, red curves) for TPU-MDI (A), TPU-IPDI (B), TPU-HMDI (C) and 1<sup>st</sup> cooling curves (D).

**Fig. S10** Micrographs of TPU microparticles in polarized light.

For TPU-IPDI and TPU-MDI: particle linear sizes are about 75x75 and 40x30 microns, respectively. Before the 1<sup>st</sup> heating (A); after the 1<sup>st</sup> heating, at 185 °C (B); after 20 hour annealing at RT, right before the 2<sup>nd</sup> heating (C). For TPU-HMDI: particle linear sizes are about 100x70 microns. Before the 1<sup>st</sup> heating (A); after the 1<sup>st</sup> heating, at 65 °C (B); after 20 hour annealing at RT, just before the 2<sup>nd</sup> heating to 185 °C (C); just after the 2<sup>nd</sup> heating, at 185 °C (D).
