## Computational Details

The PBE functional<sup>1</sup> with projector augmented wave pseudopotentials (400 eV energy cutoff)<sup>2, 3</sup> as implemented in the Vienna ab initio Simulation Package<sup>4-7</sup> was used to perform all calculations. A Gaussian-smearing method with a parameter of  $k_{\text{B}}T = 0.1$  eV was used to accelerate SCF convergence, and the calculated electronic energies were extrapolated to  $k_{\text{B}}T = 0$  eV. A Monkhorst-Pack  $k$ -point net of  $3 \times 3 \times 1$  was chosen to sample the reciprocal space for the slab calculations. Using a denser  $5 \times 5 \times 1$   $k$ -point net leads to less than 0.02 eV variation in the hydrogen binding energy on the top site. This indicates that  $k$ -point net of  $3 \times 3 \times 1$  is enough to obtain accurate energetics. The (111) and (100) index surfaces of the eight metals were simulated using a  $3 \times 3$  three-layer slab (Figure S1). During the geometric optimizations, the top two layers and adsorbates were allowed to relax, whereas the bottom layer was fixed in its bulk position. The bulk cell parameter for Ag, Au, Cu, Ni, Pd, Rh, Ir, and Pt are 4.086, 4.073, 3.615, 3.516, 3.890, 3.804, 3.900, and 3.944 Å, respectively. A vacuum of at least 30 Å was introduced to avoid interactions between replicas along the  $z$ -direction. Spin-polarized wavefunction was used for Ni and Pd, whereas spin-unpolarized one was used for the other metals.

Figure S1. Top and side views of (111) and (100) index surface of the slab model. The top (T) and hollow (H) sites are marked.

To simulate the electrochemical systems, the approach proposed by Head-Gordon et al.<sup>8</sup> was applied in this study. In this model, the Fermi energy is adjusted to a target value by changing the number of electrons in the system during each step of the geometry optimization. This allows one to fix the work function and hence the electrode potential in the calculations. The  $U$  of the electrode was calculated by relating the work function ( $\Phi$ ) of the system to the experimental work function of the standard hydrogen electrode (SHE) as follows:

$$U = \frac{\Phi - \Phi_{\text{SHE}}}{e}.$$

A value of 4.3 eV, suggested by Anderson and co-workers in their theoretical study, was used for  $\Phi_{\text{SHE}}$ .<sup>9</sup> To provide a more realistic description of the electrochemical double layer and to maintain charge neutrality of the cell, the linear Poisson-Boltzmann implicit solvation model with a Debye screening length of 3.0 Å (corresponding to 1.0 M concentration of the electrolyte) as implemented in VASPsol was used.<sup>10</sup> All the energetics reported in this study were calculated under the condition of  $U = -0.5$  V<sub>SHE</sub> and pH = 0.

A proton solvated by the water cluster ( $\text{H}^+\cdot 4\text{H}_2\text{O}$ , the Eigen proton solvated model) was transferred to  ${}^*\text{H}$  and  ${}^*\text{H}$  to locate the transition states (TSs) of the Volmer and Heyrovsky steps. This approach has been used by a previous theoretical study and the calculated barriers were in good agreement with that by transferring a proton from water bilayers to the surface.<sup>11</sup> The kinetic barriers were obtained by referencing the free energy of the transition state to the free energy of the initial state solvated by four explicit water molecules plus the free energy of a proton-electron pair.<sup>12</sup> The charge transfer coefficient is assumed to be 0.5 for the transition states, which is in the range of the experimentally determined value of 0.3 to 0.7.<sup>13</sup>

The free energies of the slab systems were calculated based on the equation as follows:

$$G = E_{elect} + ZPVE + \sum_v \frac{hv}{e^{hv/k_B T} - 1} - T \times S_{vib}$$

The vibrational frequencies were only evaluated for surface adsorbates by evaluating the partial Hessian matrix via the finite difference approach to obtain the zero-point vibrational energy (ZPVE). The low vibrational modes with a frequency  $< 50 \text{ cm}^{-1}$  were adjusted to have a value of  $50 \text{ cm}^{-1}$  to avoid a spurious contribution to the entropy. The constant electrode potential method applied in this work leads to different numbers of electrons for each stationary point along the reaction path, and therefore the calculated G needs to be corrected based on the following equation:

$$G^{\text{corr}}(U) = G(U) - (N_{e,U} - N_{e,0})\mu_e(U),$$

where  $N_{e,U}$  and  $N_{e,0}$  are the number of electrons in the system under the target  $U$  and zero charge, respectively, and  $\mu_e(U)$  is the chemical potential of the electrons under  $U$  and is equal to the Fermi energy.

The vibrational frequencies for each stationary point were examined. Each transition state has one imaginary frequency, corresponding to the reaction direction. In addition, there are no imaginary frequencies for reactants, intermediates, and products. The transition states were located using the dimer method<sup>14,15</sup> and further verified by vibrational frequency calculations where only one imaginary frequency was present.

The ALMO-EDA analysis was performed using the Q-Chem package with the same PBE functional. For the basis sets, LanL2DZ was used for Pt, and 6-31G\*\* was used for the others. During optimization, the coordinates for all Pt atoms were fixed in their bulk positions.
