Section S1. Experimental Section

General Remarks for Characterization: ^1H and ^{13}C NMR spectroscopy were conducted on an AVANCE III 400 Ascend Bruker BioSpin instrument at room temperature (r.t). Infrared (FTIR) spectra (range: 4000 to 500 cm^{-1}) was record by BRUKER TENSOR 27 machine. Elemental analyses (C, H, N and S content) were performed with a ThermoFlash 2000 elemental analyzer. Mass spectrometric analyses were carried out on Bruker-Daltonics, MicroTOF-Q II mass spectrometer. Spectrophotometric measurements for absorption study were done using a quartz cuvette with a path length of 1 cm on a Varian UV/Vis spectrophotometer (Model: Cary 100). Thermogravimetric analysis (TGA) was conducted on a “METTLER TOLEDO” TGA/DSC 1 Module with a heating rate of 10 $^{\circ}\text{C min}^{-1}$ with a sensitivity of 10 mg in the temperature range of 0-800 $^{\circ}\text{C}$ and the TGA data was analyzed by “STAR^e Software” under a static N_2 atmosphere. Stopped-flow spectrometry was carried out by a BioLogic Sciences Instruments (Seyssinet-Pariset, France) SFM4000 apparatus. The cyclization products throughout catalysis were quantitatively identified by GC experiments using GC-MS QP 2010 Ultra mass spectrometer from Shimadzu Analytical India Pvt. Ltd.

Section S2. X-ray crystallography

Single crystal X-ray structural studies of Mannich base ligand (**HL**²), complex **1** and complex **2** were performed on a CCD Agilent Technologies (Oxford Diffraction) SUPER NOVA diffractometer, among which **HL**² has reported with CCDC **1882115**.¹ Data for both the compounds were collected at 150-293 K using a graphite-monochromated $\text{MoK}\alpha$ radiation ($\lambda_{\alpha} = 0.71073 \text{ \AA}$). The strategy for the data collection was evaluated by using the CrysAlisPro CCD software.² The data were collected by the standard ‘phi-omega scan techniques and were scaled and reduced using CrysAlisPro RED software. The structures were solved by direct methods using SHELXS-97 and refined by full matrix least-squares with SHELXL-97, refining on F^2 .³ The positions of all the atoms were obtained by direct methods. All non-hydrogen atoms were refined anisotropically. The remaining hydrogen atoms were placed in geometrically constrained positions and refined with isotropic temperature factors, generally $1.2U_{\text{eq}}$ of their parent atoms. The crystal and refinement data are summarized in Table 1 and corresponding bond lengths, bond angles and other crystallographic details are summarized in Table S2-S7.

Section S3. Materials and methods

S3.1. Hirshfeld surface analysis

In addition, Hirshfeld surface analysis (Figure S8) has been carried out to corroborate the possible supramolecular interactions of the synthesized complexes as described in Figure S7. The molecular Hirshfeld surface⁴ is formed based on the electron distribution of a molecule and has been determined as the sum of spherical atom electron densities.⁵ For a given crystal structure and set of spherical atomic electron densities, the Hirshfeld surface is unique.⁶ Equation (1), which is based on both d_e and d_i , and the van der Waals radii of the atom give the normalized contact distance (d_{norm}), where d_e is the distance from the point to the nearest nucleus external to the surface, and d_i is the distance to the nearest nucleus internal to the surface. The 2D fingerprint plot provides a summary of intermolecular contacts in the crystal.⁶⁻⁷ The Hirshfeld surfaces presented here were generated using Crystal Explorer 3.1.⁸ The symmetrically generated counterpart of the structures was not taken into account in Hirshfeld surface calculations.⁹

$$d_{norm} = \frac{d_i - r_i^{vdw}}{r_i^{vdw}} + \frac{d_e - r_e^{vdw}}{r_e^{vdw}} \dots \quad \dots (1)$$

S3.2. Ammonia Assay

Ammonia was analyzed by using an indophenol assay procedure as per earlier report.¹⁰

Reagents Solutions: NH_3 containing H_3BO_3 , $\text{Cl}_2\text{-H}_2\text{O}$, 8% PhOH in H_2O , 3N NaOH

Attention: Ammonia (NH_3) free water should be used throughout the assay. These reagents can be stored in a refrigerator for about 1 month without decomposition. Though, here the experiments have been carried out with freshly prepared solution!

- Preparation of Solutions: Step I- Preparation of $\text{NH}_3\text{-H}_3\text{BO}_3$ solution

Known volume (< 250 mL) of water was taken into the collection chamber and proper apparatus was set-up followed by the maintenance of optimized reaction conditions for ammonia production. After urea hydrolysis, the NH_3 mixed water solution was taken in a conical flask and boric acid (13.88 g) was added into it. The volume was made up by water up to 250 mL to have the stock solution followed by the transfer 25 mL solution in a 50 mL of volumetric flask.

- Step II- Preparation of $\text{Cl}_2\text{-H}_2\text{O}$

5% alkaline hypochlorite (NaOCl , 180 mL) was added to 12M of hydrochloride (HCl , 20 mL) acid, which was poured into 800 mL water (H_2O) to produce 0.12 mol of molecular chlorine solution.

Color development procedure: After filled by $\text{H}_3\text{BO}_3\text{-NH}_3$ solution, 5 mL of $\text{Cl}_2\text{-H}_2\text{O}$ and 5 mL of 8% phenol solutions were added in each 50 mL volumetric flask. Further the volumetric flasks were heated in the hot plates at $100\text{ }^\circ\text{C}$ for 3 min and cooled down rapidly. Add 5 mL of 3M NaOH and dilute to volume. The blue color developed fully from faint yellow within 5 min (See the following reaction). Read the absorbance of the blue solutions in a 1 cm cuvette at 629 nm against a reagent blank. When the complexes and substrates themselves were assayed, no absorbance at 629 nm was observed. The concentrations of unknown ammonia solutions have been obtained from the standard calibration curve (Figure S15).

A calibration curve was obtained by adding aliquots of standard NH_3 solution (30-330 ppm), which have been prepared as abovementioned color developing method. Only standard NH_3 solution has been used instead of Step-I.

▪ Step III- Preparation of standard NH_3 solution for calibration

A stock solution was prepared containing 1000 ppm of NH_3 by dissolving 3.145 g of dry NH_4Cl in 1 L of ammonia-free water.

Quantitative measurement of ammonia¹¹

Determination of the concentration of unknown samples:

O.D value of unknown samples are 0.1288 and 0.1395 for dinickel mimetics **1** and **2**, respectively (from the reaction between 2 mmol urea and 0.02 mmol of each complex at $59\text{ }^\circ\text{C}$ in aqueous medium for 2 h). Each measurement replicates for three times and average value has been considered for final quantitative evaluation.

As, from the Lambert- Beer's law; $A = \epsilon cl \dots$... (i)

And from the linear equation; $Y = mX + C \dots$... (ii)

Where, A = Absorbance or optical density (O.D), ϵ = Molar extinction coefficient, c = Concentration, l = Path length of the cell (here 1 cm), m = Slope and C = Intercept

Which means at $C = 0$, the equation (ii) becomes to $Y = mX \dots$... (iii)

Comparing equations (i) and (iii), we get; $m = \epsilon$

From the standard calibration curve as discussed above, we have

Slope (ϵ) = $m = 0.0026$ (by fixing the intercept, $C = 0$)

Now, for the determination of unknown sample concentration;

By using equation (i):

$$A = \epsilon cl$$

or, $0.1288 = 0.0026 \times c \times 1$ (considering dinickel mimetic **1**)

or, $c = 49.54$ ppm

Now, $1 \text{ ppm} = 1 \text{ mg/L}$

So, $49.54 \text{ ppm} = 49.54 \text{ mg/L}$

Now, to calculate the mole of NH_3 production in the reaction is:

So, molarity = $49.54 \text{ (mg/L)} / 17.031 \text{ (g/mol)} = 49.54 / (17.031 \times 1000) \text{ (mol/L)} = 49.54 / 17.031$
 $\text{(mmol/L)} = 2.9088 \text{ (mmol/L)}$

Similarly, for dinickel mimetic **2** the value is $53.65 \text{ ppm} \equiv 3.15036 \text{ (mmol/L)}$.

Section S4. Figures

Figure S1. (a) ^1H (400.13 MHz, 298K, CDCl_3) and (b) ^{13}C (100.61 MHz, 298K, CDCl_3) NMR spectra of **HL**¹. Letters denote the chemical environment for each hydrogen and carbon.

Figure S27. (a) ESI-MS spectra: molecular ion peak at $M + H^+ = 306.1$ and $(M+2) + H^+ = 308.1$ responsible for -Cl pattern (in HPLC MeOH) and (b) FTIR spectra (KBr pallet) of **P-6**.

Figure S28. (a) ^1H NMR and (b) ^{13}C NMR of **P-6** (in chloroform-d, 25 °C).

Figure S29. (a) ESI-MS spectra: molecular ion peak at $M + H^+ = 290.1$ (in HPLC MeOH) and (b) FTIR spectra (KBr pallet) of **P-7**.

Figure S30. (a) ^1H NMR and (b) ^{13}C NMR of **P-7** (in chloroform-d, 25 °C).

Figure S31. Thermal stability diagram of synthesized urease mimetics by TGA analysis. At catalytic temperature ($T = 75\text{ }^{\circ}\text{C}$), complex 1 decomposes more rapidly with respect to its analogous 2.

Figure S32. Normal (left) and UV (right) light incorporated hand-held camera images of **P-1** solution in aqueous phase.

Figure S33. Confocal laser scanning microscopy (CLSM) images of human cervical cancer cell (HeLa) lines. This shows the site selection ability of the synthesized AmCyPYs (here P-1) in contrast to the reported cancer cell staining dye viz. Hoechst 33342.

Section S5. Schemes

Scheme S1. Syntheses of Mannich base ligands, HL^{1/2} and corresponding urease mimetics.

Scheme S2. Interactions between urea and dinickel centres in case of mimetic 2.

Scheme S3. Plausible mechanism for urease mimetics catalyzed synthesis of 2-amino-3-cyanopyridines (AmCyPys).

Table S1. Selected bond lengths (Å) and bond angles (°) for complexes **1** and **2**.
