## 1. Crystallographic details

### 1.1 Overview

Single crystals suitable for X-ray diffraction analysis were selected in Fomblin YR-1800 perfluoropolyether oil (Alfa Aesar) at ambient temperature and mounted on a glass fiber. During the measurement, the samples were cooled to 123(2) K. Diffraction data were collected on a Bruker D8 QUEST diffractometer and a Bruker Kappa Apex II diffractometer using graphite monochromated Mo-K ${ }_{\alpha}$ radiation. Structure solutions were found by direct methods (SHELXS-97 or SHELXS-2013) ${ }^{1}$ and were refined by full-matrix least-squares procedures on $F^{2}$ (SHELXL-2013) ${ }^{2}$. All non-hydrogen atoms were anisotropically refined unless stated otherwise. Hydrogen atoms were included at calculated positions with fixed thermal parameters unless stated otherwise. The unit cell of $5-\mathrm{PF}_{6}$ contains seven dichloromethane molecules and the unit cell of 6 contains eight dichloromethane molecules, which have been treated as a diffuse contribution to the overall scattering without specific atom positions by SQUEEZE/PLATON.

## 2. Experimental section

### 2.1 General information

All operations were carried out in an atmosphere of dry argon using Schlenk and glove box techniques. Solvents for reactions were dried and saturated with argon by standard methods and freshly distilled prior to use. Solvents for chromatography were used as purchased from commercial sources. NMR spectra were recorded at 298 or 300 K using Bruker Avance 250, 300 or 500 MHz spectrometers. In ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C} N M R$, the chemical shifts were internally referenced to the solvent residual peak and in ${ }^{31} \mathrm{P} N M R, \mathrm{H}_{3} \mathrm{PO}_{4}$ was used as external standard. For the simulation of NMR spectra, the experimental ${ }^{1} \mathrm{H}$ NMR spectrum was transferred to $g N M R^{3}$. The full line shape iteration procedure of gNMR was applied to match the simulated to the experimental spectrum. Elemental analyses were performed with a Thermo Finnigan Flash EA 1112 Series. Spectro-electrochemical measurements were performed in $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ solution with $0.26 \mathrm{M} n-\mathrm{Bu}_{4} \mathrm{NPF}_{6}$ as supporting electrolyte in an IR cell equipped with silver wire and platinum mesh. The compounds $\left[T p * W(C O)_{3}\right]$, $\left[\mathrm{Tp} * \mathrm{~W}(\mathrm{CO}) I\left(\mathrm{Ph}_{2} \mathrm{PC} \equiv \mathrm{CH}\right)\right],{ }^{4} \quad\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Fe}^{2}\right] \mathrm{PF}_{6}{ }^{5}{ }^{5}$ 2-ethynylpyridine, ${ }^{6} \quad\left[\mathrm{Ru}(\mathrm{bpy})_{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}\right] \mathrm{PF}_{6}{ }^{7}{ }^{7} \quad\left[\operatorname{Ir}(\mathrm{ppy})_{2} \mathrm{Cl}\right]_{2},{ }^{8}$ $\left[\mathrm{Ru}(\mathrm{dppp})_{2} \mathrm{Cl}_{2}\right],{ }^{9}\left[\mathrm{Ru}(\mathrm{bpy})_{2}(\mathrm{ppy})\right] \mathrm{PF}_{6}{ }^{10}$ were synthesized according to literature procedures. All other reagents were used as purchased from commercial sources.

### 2.2 Synthetic procedures

## PyC $\equiv \mathrm{CCH}_{3}$

A yellow solution of 2-ethynylpyridine ( $2.66 \mathrm{~g}, 25.80 \mathrm{mmol}$ ) in 150 mL THF had been cooled to $-78^{\circ} \mathrm{C}$ for 15 min , before $n$-butyllithium ( 2.5 M solution in $n$-hexane, $14.4 \mathrm{~mL}, 36.11 \mathrm{mmol}$ ) was slowly added. The resulting red solution was stirred for 15 min at $-78^{\circ} \mathrm{C}$ to complete the reaction. After adding Mel ( $2.89 \mathrm{~mL}, 46.42 \mathrm{mmol}$ ) the solution turned orange and was stirred for 2 h at low temperatures. At room temperature the volatiles were removed in vacuo leaving an oily residue, which was purified on silica using a 3:2 mixture of $n$-hexane and ethyl acetate. Yield: $2.51 \mathrm{~g}, 83 \%$.

## [ $\left.\mathrm{Tp}{ }^{*} \mathrm{~W}(\mathrm{CO})!\left(\mathrm{Ph}_{2} \mathrm{PC}=\mathrm{CCH}_{3}\right)\right] 1$

A blue solution of $\left[\mathrm{Tp}{ }^{*} \mathrm{~W}(\mathrm{CO}) I\left(\mathrm{Ph}_{2} \mathrm{PC} \equiv \mathrm{CH}\right)\right](800 \mathrm{mg}, 0.90 \mathrm{mmol})$ in 45 mL THF had been cooled to $-78{ }^{\circ} \mathrm{C}$ for 15 min , before $n$-butyllithium ( 2.5 M solution in $n$-hexane, $0.48 \mathrm{~mL}, 1.20 \mathrm{mmol}$ ) was slowly added. The resulting deep blue solution was stirred for 15 min at $-78^{\circ} \mathrm{C}$ to complete the reaction. After adding $\mathrm{Mel}(0.24 \mathrm{~mL}, 3.86 \mathrm{mmol})$ the solution was stirred for 4 h at low temperatures. Finally, all volatiles were removed at ambient temperature in vacuo, the green residue was purified on silica using a 1:1 mixture of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and petroleum ether. ## [Tp*W(CO)Br(PyC三CCH3)] 2

A red solution of $\left[\mathrm{Tp}^{*} \mathrm{~W}(\mathrm{CO})_{3}\right](6.0 \mathrm{~g}, 9.88 \mathrm{mmol})$ and 2-(prop-1-yne-1-yl)pyridine ( $1.16 \mathrm{~g}, 9.88 \mathrm{mmol}$ ) in $110 \mathrm{mLCH} \mathrm{Cl}_{2}$ was cooled to $0^{\circ} \mathrm{C}$ and treated with solid $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Fe}\right] \mathrm{PF}_{6}(3.27 \mathrm{~g}, 9.88 \mathrm{mmol})$ in small portions within 30 min . After stirring at room temperature for 2 h in situ IR-measurements confirmed the complete formation of $\left[\mathrm{Tp} * \mathrm{~W}(\mathrm{CO})_{2}\left(\mathrm{PyCCCH}_{3}\right)\right]^{+}[\tilde{v}=2565(\mathrm{w}, \mathrm{BH}), 2057,1920(\mathrm{~s}, \mathrm{CO})]$. All volatiles were removed in vacuo. The brown residue was dissolved in 110 mL THF and solid $\mathrm{NBu}_{4} \mathrm{Br}(3.84 \mathrm{~g}$, 11.91 mmol) was added. After 2 h at room temperature the completion of the CO substitution was confirmed by in situ IR spectroscopy. All volatiles were removed in vacuo and the crude product was washed several times with methanol. After drying in vacuo the residue was purified on silica using a 10:1 mixture of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathrm{CH}_{3} \mathrm{CN}$. Yield: $2.57 \mathrm{~g}, 35 \%$.

## $\left[\mathrm{Tp} * \mathrm{~W}(\mathrm{CO})!\left(\mathrm{Ph}_{2} \mathrm{PC} \equiv \mathrm{CCH}_{2}\right)\right]_{2}[3]_{2}$

A green solution of $1(100 \mathrm{mg}, 0.11 \mathrm{mmol})$ in 15 mL THF had been cooled to $-78{ }^{\circ} \mathrm{C}$ for 15 min , before $n$-butyllithium ( 2.5 M solution in $n$-hexane, $0.06 \mathrm{~mL}, 0.15 \mathrm{mmol}$ ) was slowly added. The resulting red solution was stirred for 5 min at $-78{ }^{\circ} \mathrm{C}$. After slowly adding a solution of $\left[\mathrm{RuCl}_{2}(\mathrm{dppp})_{2}\right] \mathrm{PF}_{6}(128 \mathrm{mg}$, 0.11 mmol ) in 3 mL THF, the reaction mixture was stirred at low temperatures for 3 h . A green solution of $1(100 \mathrm{mg}, 0.11 \mathrm{mmol})$ in 8 mL THF had been cooled to $-78^{\circ} \mathrm{C}$ for 15 min , before $n$-butyllithium ( 2.5 M solution in $n$-hexane, $0.06 \mathrm{~mL}, 0.15 \mathrm{mmol}$ ) is slowly added. The resulting red solution was stirred for 10 min at $-78^{\circ} \mathrm{C}$. In the dark a solution of $\mathrm{AuSMe}_{2} \mathrm{Cl}(33 \mathrm{mg}, 0.11 \mathrm{mmol})$ in 5 mL THF was slowly added, the reaction mixture was stirred at low temperatures for 3 h . All volatiles were removed in vacuo and $15 \mathrm{mLCH}_{2} \mathrm{Cl}_{2}$ was added. After filtration, the solution was concentrated and crystallized by slow diffusion of $n$-pentane into the concentrated solution. Yield: $48 \mathrm{mg}, 38 \%$ (with both isomers being present). The isomers were separated by fractionated crystallisation, showing that the unlike- 5 is more soluble in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ compared to like-5.

While we were able to isolate the unlike-isomer in pure form allowing full characterization by NMR and IR spectroscopy as well as cyclic voltammetry, the like-isomer was solely investigated in a 2:3 mixture with the unlike-isomer by ${ }^{31}$ P NMR and IR spectroscopy. To proof the different connectivity, XRD analysis was performed for both isomers.

### 2.4 CV measurements

Cyclic voltammetry was performed on a Princeton Applied Research VersaSTAT 3 unit. A threeelectrode arrangement with a glassy carbon working electrode, a platinum wire counter electrode and an $\mathrm{Ag} / \mathrm{AgBF}_{4}$ in $\mathrm{CH}_{3} \mathrm{CN}$ reference electrode and $0.1 \mathrm{M} n-\mathrm{Bu}^{2} \mathrm{NPF}_{6}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as supporting electrolyte was employed. The ferrocene/ferrocenium ( $\mathrm{Fc} / \mathrm{Fc}^{+}$), acetylferrocene/acetylferrocenium ( $\mathrm{AcFc} / \mathrm{AcFc}^{+}$) or diacetylferrocene/diacetylferrocenium ( $\mathrm{Ac}_{2} \mathrm{Fc} / \mathrm{Ac}_{2} \mathrm{Fc}^{+}$) redox couple were used as internal standard. The redox potentials referenced to the ferrocene derivatives have been corrected to reference all redox couples to ( $\mathrm{Fc} / \mathrm{Fc}^{+}$). The quasi-reversible character of electron transfer processes have been supported by variation of the scan rates (Figures S22, S23, S24).

### 2.4 UV-vis and luminescence measurements

Steady-state UV-vis absorption spectra were recorded with an Agilent 8453 and steady state emission spectra with an Agilent Cary Eclipse spectrometer. The samples were placed in a 1 cm path fused silica cuvette, and dissolved oxygen was removed by bubbling with argon for about 2 min . Corrected emission spectra were obtained via a calibration curve supplied with the instrument. Photoluminescence quantum yields ( $\varphi_{\text {PL }}$ ) were extracted from corrected spectra on a wavelength scale ( nm ). A solution of $\left[\mathrm{Ru}(\mathrm{bpy})_{3}\right] \mathrm{Cl}_{2}$ (Aldrich) in deaired water (spectrophotometric grade, Alfa Aesar; $\varphi_{\text {PL }}=0.043^{12}$ ) or $\operatorname{Ir}(p p y)_{3}$ (Aldrich) in deaired toluene (spectrophotometric grade, Acros Organics; $\varphi_{\mathrm{PL}}=0.73^{13}$ ) was applied as standard. Sample and luminescence standard were excited at 450 or 365 nm , respectively, with an absorbance of about 0.1 at the excitation wavelength for both sample and standard.

### 2.5 TD DFT calculations

DFT calculations were carried out as closed shell $(S=0)$ calculations using the ORCA program package, version 4.1.1. ${ }^{14}$ Molecular geometries were optimized without truncation and symmetry constraints in the gas phase using the BP86 functional. ${ }^{15}$ Quasi-relativistic effective core potentials were used for $W$ (ECP46MBW) and Ru (ECP28MBW). ${ }^{16}$ Split valence triple $\zeta$-basis sets (def2-TZVP) of the Ahlrich group ${ }^{17}$ and respective auxiliary basis sets were applied. ${ }^{18}$ Dispersion was accounted for by the atom-pairwise dispersion correction with the Becke-Johnson damping scheme (D3BJ). ${ }^{19}$ In doing so a reasonable match between the calculated and the experimentally determined structures for 2, $\left[\mathrm{Ru}(\mathrm{bpy})_{2}(\mathrm{ppy})\right]^{+}$(for comparison) and $\mathbf{6}^{+}$were achieved. Frequency calculations were
performed to identify all stationary points as minima. The Cartesian coordinates are given in Table S7 and S8. TD DFT calculations were performed using the B3LYP functional in combination with split valence triple $\zeta$-basis sets as mentioned above. The range to 380 nm was covered by 10 (2), 20 $\left[\mathrm{Ru}(\mathrm{bpy})_{2}(\mathrm{ppy})\right]^{+}$and $30\left(6^{+}\right)$calculated singlet/singlet transitions, respectively. Selected states with high oscillator strength are given in Tables S4 to S6 and the difference densities for essential transitions are depicted in Figures S29 to S31. Attempts with higher level functionals like PBEO (for geometry optimization) or an all electron ZORA approach (TD DFT) did not improve the match of the calculated with experimental data.

### 2.6 Transient absorption spectroscopy

A setup was used based on a regenerative Ti:Sapphire amplifier system (CPS-2001, Clark MXR) providing ultrashort laser pulses centred at 775 nm with a repetition rate of 1 kHz . Excitation (pump) pulses centred at 720 nm were generated by a noncollinear optical parametric amplifier (NOPA). The dispersion of the NOPA pulses was minimized using a compressor based on fused-silica prisms resulting in a pulse duration of 70 fs . The final wavelength for excitation of 360 nm was reached via frequency doubling using a 0.7 mm thick BBO crystal. Absorption changes were probed over the complete visible spectral range with a white-light continuum generated by focusing a small fraction of the Ti:sapphire output into a rotating $\mathrm{CaF}_{2}$ substrate. The polarisation of the probe pulses was set to magic angle ( $\sim 54.7^{\circ}$ ) relative to that of the pump-pulses. Pump and probe pulses were focused onto the sample to overlap. Their spot diameters were approximately $444 \mu \mathrm{~m}$ for the pump and $133 \mu \mathrm{~m}$ for the probe. After passing through the sample, the probe was spectrally dispersed by a prism, and the TA changes were recorded with a photodiode array detector with 512 pixels. The chirp of the probe signal was corrected numerically in a data processing procedure. The substances were dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ of spectroscopy grade. The solution was measured in a quartz cuvette with a thickness of 1 mm . The obtained data was analyzed using a global fit. In this procedure the multiexponential model function $F(\lambda, t)=\sum_{i}^{N} D A S_{i}(\lambda) \cdot \exp \left(-\mathrm{t} / \tau_{i}\right)$, convoluted with the temporal response of the pump-probe setup, is fitted to the complete set of time dependent transient absorption spectra. In the present case three exponential decay components were necessary, i. e. $N$ $=3$, to reproduce the data with satisfying accuracy. Thereby, the time constant of the third component was set to infinity, to describe a long living contribution which persists much longer than the experimentally accessible time range.
