Scheme S2. A speculative catalytic cycle for the Suzuki-Miyaura coupling reaction catalyzed by
Generally, the reaction proceeds via a classical catalytic cycle of Suzuki-Miyaura coupling reaction involving the O,N,C-chelated Ni(0) active species. Then an oxidative addition of the aryl chloride substrate occurs, forming the Ar—Ni(II) intermediate. Transmetalation of the aryl group from the boron to the nickel center led to the diaryl intermediate. An aryl group bearing an electron-withdrawing group enhances its transfer on the nickel center, whereas an aryl group with an electron-donating group disfavors the process. The diaryl intermediate then undergoes a reductive elimination to give the couple product. The oxidative addition step is most probably the r.d.s of the catalytic cycle. However, a small amount of the O,N,C-chelated Ni(0) active species can also undergo a catalyst degradation to form off-loop homogeneous ligand-free Ni(0) or heterogeneous Ni(0) nanoparticles (See entry 8 in Table 3). The in situ formed IMes ligand from the IMes-HCl additive is able to capture these Ni(0) species to form Ni⁰(IMes), which can then catalyze the formation of the couple product in an auxiliary cycle. For activated aryl chloride substrate, the oxidative addition step is much faster than the degradation step (rate constant $k_1 \gg k_2$) and thus the product yield enhancement is low (CF₃ = 1.7). But in the case of de-activated substrates, the oxidative addition step becomes slower. Hence, more Ni(0) species enters the auxiliary cycle such that higher product enhancement ratios were observed (OMe = 3.7).

**Single-crystal X-ray diffraction.** Structural data of 3b 3c, and 3c″ were collected on a Bruker SMART APEX II equipped with a CCD area detector. Data collection were carried out at 150(2) K.
using MoKα radiation (λ = 0.71073 Å). The unit cell parameters were obtained by least-squares refinement. Data collection and reduction were performed using the Bruker APEX and SAINT software. Absorption corrections were performed using the SADABS program. All the structures were solved by direct methods and refined by full-matrix least squares methods against F² with the SHELXL software package. All non-hydrogen atoms were refined in anisotropic manners. All hydrogen atoms were positioned at calculated positions and riding refinements were then applied. The structure of 3b was refined as a non-merohedral twin. The structure of 3c contains disordered DMF solvent molecules and their structural factor contributions were removed by the SQUEEZE procedure. CCDC files numbers: 2100759 (3b), 2100760 (3c’’), and 2100761 (3c).
