Figure S1 Comparison between measured (red points) and calculated HONO mixing ratio during the solar eclipse, using actual eclipse photolysis frequencies (solid blue line) and (hypothetical) non-eclipse photolysis frequencies (dotted blue line). Fitting optimised throughout the pre-eclipse hour, eclipse period, and post-eclipse hour. Shading indicates eclipse duration from first to last contact. Source scenarios as defined in Table 1.
Figure S2 Comparison between simulated HONO and measured HONO for days preceding and following the eclipse.
